OFFICERS OF THE SECTIONS

SECTION OF MEDICINE

Chairman, George D Henderson, Holyoke, *secretary*, Albert A Hornor,
 Boston

SECTION OF SURGERY

Chairman, Howard M Clute Boston *secretary*, Charles F Twomey East Lynn
 EXECUTIVE COMMITTEE—Archibald M Fraser, Boston (1 year), Stanley J G
 Nowak, Belmont and Boston (2 years), Edward L Young, Jr., Brookline and
 Boston (3 years)

SECTION OF PEDIATRICS

Chairman Leroy T Stokes Haverhill, *secretary*, Gerald N Hoeffel, Cambridge
 EXECUTIVE COMMITTEE—Harold L Higgins, Newton *chairman*, Philip H
 Sylvester, Boston, James Marvin Bary, Belmont and Brookline

SECTION OF OBSTETRICS AND GYNECOLOGY

Chairman Christopher J Duncan, Brookline, *vice chairman*, Arthur F G
 Edgelow, Springfield, *secretary*, George Van S Smith, Brookline

SECTION OF RADIOLOGY

Chairman, Stanley A Wilson, Salem, *secretary*, George Levene, Chestnut Hill
 and Boston

SECTION OF PHYSIOTHERAPY

Chairman, Wilmot L Marden, Lynn, *secretary*, Howard Moore, Newton and
 Boston

SECTION OF DERMATOLOGY AND SYPHILIOLOGY

Chairman, John G Downing, Newton and Boston, *secretary*, G Marshall
 Crawford Lincoln and Brookline

OFFICERS OF THE DISTRICT MEDICAL SOCIETIES FOR 1943-1944

BARNSTABLE—*President*, Julius G Kelley, Pocasset, *vice president*, Joseph N
 Kelly, Orleans, *secretary*, Frank Travers Barnstable, *treasurer*, Harold F Rowley,
 Harwich Port, *librarian*, Carroll H Keene Chatham

BERKSHIRE—*President*, Charles T Leslie, Pittsfield, *vice president*, Floyd R
 Smith, Pittsfield *secretary*, N Newall Copeland Pittsfield, *treasurer*, Daniel N
 Beers, Pittsfield, *legislative and public relations counselor*, Patrick J Sullivan,
 Dalton

BRISTOL NORTH—*President*, Joseph L Murphy, Taunton *vice president*,
 William M Stobbs Attleboro *secretary*, William J Morse Jr., Attleboro *treasurer*,
 Joseph V. Chazy, Taunton *executive counselor*, William H Allen, Mansfield,
legislative counselor, Joseph L Murphy, Taunton, *public relations counselor*,
 James H Brewster, Attleboro

BRISTOL SOUTH—*President*, Edward F Shay Fall River *vice president*, Russell
 Wood, New Bedford *secretary and treasurer*, Albert H Sterns New Bedford,
public relations counselor, Harold E Perry, New Bedford

ESSEX NORTH—*President*, Robert C Hannigan Amesbury, *vice president*,
 John T Bata Lawrence, *secretary*, Harold R Kurth Lawrence *treasurer*, Guy L
 Richardson Haverhill, *auditor*, Alphonse J Peter, Newburyport *executive coun-*
cilor, Frank W Snow, Newburyport, *legislative counselor*, Edward H Ganley,
 Methuen *public relations counselor*, Elmer S Bagnall, Groveland

ESSEX SOUTH—*President*, Paul E Tivnan Salem, *vice president*, Edwin D
 Reynolds Danvers *secretary*, Henry D Stebbins Marblehead, *treasurer*, Charles F.
 Deering Danvers *executive and public relations counselor*, Loring Grimes, Swamp-
 scott, *legislative counselor*, Charles A Worthen Lynn

FRANKLIN—*President*, Arthur W Hayes Greenfield, *vice president*, Kenneth H-
 Rice South Deerfield *secretary and treasurer*, Harry L Craft, Ashfield, *executive*
counselor, Frederick J Barnard, Greenfield, *legislative counselor*, Howard M Kemp,
 Greenfield, *public relations counselor*, William J Pelletier, Turners Falls

HAMPDEN—*President*, Edward A Knowlton Holyoke, *vice president*, Sidney R
 Carley Palmer, *secretary and treasurer*, Wayne C Barnes, Springfield, *executive*
counselor, George I Steele, Springfield *legislative counselor*, William A R.
 Chapin, Springfield, *public relations counselor*, Patrick E Gear, Holyoke

HAMPSHIRE—*President*, Arthur N Ball Northampton *vice president*, Joseph D.
 Felton Northampton, *secretary and treasurer*, Mary P Snook, Chesterfield, *librarian*,
 Abbe M O'Keefe, Northampton *executive counselor*, L Beverly Pond, Eastham-
 pton *legislative counselor*, Arthur N Ball Northampton, *public relations counselor*,
 Alfred J Bonnevillie Hatfield

MIDDLESEX EAST—*President*, Roger M Burgoynes, Winchester, *vice president*,
 Joseph H Kerrigan Stoughton *secretary*, Roy W Layton, Melrose, *treasurer*,
 Albert F Small Melrose, *librarian*, Raymond E Militzer, Woburn, *legislative*
counselor, John M Wilcox Woburn *public relations counselor*, J Harper Blaisdell,
 Woburn

MIDDLESEX NORTH—*President*, Herbert M Larrabee, Tewksbury, *vice president*,
 James J Cassidy, Lowell, *secretary*, Brendan D Leahy, Lowell, *treasurer*, Mason D
 Bryant, Lowell *executive counselor*, William M. Collins, Lowell, *legislative coun-*
cilor, Warren H Sherman, Lowell, *public-relations counselor*, Daniel J Ellison,
 Lowell

MIDDLESEX SOUTH—*President*, Harold G Giddings, Newton Centre *vice*
president, Brainerd F Conley, Malden, *secretary*, Alexander A. Levi, Newton
 Centre, *treasurer*, Fabian Packard, Belmont, *orator*, George W. Thorn, Cambridge,
executive counselor, Dwight O'Hara, Waltham; *legislative counselor*, Brainerd F.
 Conley, Malden, *public relations counselor*, John P. Neilligan, Cambridge.

NORFOLK—*President*, John C V. Fisher, West Roxbury, *vice president*, Albert
 Ehrenfried, Brookline *secretary*, Timothy F. P. Lyons, Milton, *treasurer*, Frederick
 Reis, Jamaica Plain, *executive counselor*, Carl Bearse, Boston; *legislative counselor*,
 John C V. Fisher, West Roxbury, *public relations counselor*, Norman A Welch,
 West Roxbury

NORFOLK SOUTH—*President*, George V Higgins, Randolph, *vice president*,
 Henry A Robinson Hingham, *secretary and librarian*, Eben K Jenkins South
 Braintree, *treasurer*, Frank W. Crawford, Holbrook; *executive counselor*, Daniel B
 Reardon, Quincy; *legislative counselor*, David L. Belding, Hingham, *public relations*
counselor, Fred A. Bartlett, Wollaston.

PLYMOUTH—*President*, Edward L. Perry, Middleboro; *vice-president*, Peirce H
 Leavitt, Brockton, *secretary*, Ralph C. McLeod, Brockton; *treasurer*, Alton L.
 Hurlburt, East Bridgewater, *librarian*, John H. Weller, Bridgewater; *executive*
counselor, Peirce H Leavitt, Brockton; *public relations counselor*, Charles D. McCann,
 Brockton

SUFFOLK—*President*, James P. O'Hare, Boston; *vice president*, Howard M
 Clute, Boston, *secretary*, Hollis L Albright, Boston; *treasurer*, Richard S Eustis,
 Boston, *executive counselor*, Donald Munro, Boston, *legislative counselor*, William B
 Breed, Boston, *public relations counselor*, Albert A. Hornor, Boston.

WORCESTER—*President*, Andrew E O'Connell, Worcester, *vice president*, Ben
 jamin H Alton, Worcester, *secretary*, Leslie P. Leland, Worcester, *treasurer*,
 Edward P. Disbrow, Worcester, *executive counselor*, Ralph S Perkins, Worcester;
legislative counselor, Lester M. Felton, Worcester; *librarian and public-relations*
counselor, John M Fallon, Worcester.

WORCESTER NORTH—*President*, Herman D. Bone, Gardner; *vice president*,
 Rudolf F Bachmann, Fitchburg, *secretary*, Edward A. Adams, Fitchburg; *treasurer*,
 Frederick H. Thompson, Jr., Fitchburg; *executive counselor*, C. Bertram Gay,
 Fitchburg, *legislative counselor*, Francis A. Reynolds, Athol; *public relations coun-*
cilor, James G Simmons, Fitchburg

SUBJECT INDEX

A

- ABDOMEN surgery [Allen] 127 - mp
 ABSENTEEISM in industry 466 - c
 medical aspects of [Daniels] 773 - MMS
 ADDISON'S DISEASE [Lawson & others] 480*
 ADOLESCENTS, blood pressure of [Lawrence] 381*
 AGRICULTURE and war (See Back to land) 439 - c
 ALCOHOLISM, treatment [Thimann] 333*
 ALIMENTARY-TRACT disturbances secondary to emotional
 or physical trauma [Jones] 612 - mp
 (WILLIAM) ALLAN [White] 698 - c
 ALLERGIC shock, death from [Hunt] 502*
 AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY 808 - n
 AMERICAN COLLEGE OF SURGEONS 268 - misc
 AMERICAN RED CROSS 377 - c
 ANCIENT OF DAYS 296 - c
 (See Virile New Yorkers) 626 - c
 ANEMIA, acute hemolytic following sulfadiazine [Boyer]
 566*
 hemolytic, isoimmunization with Rh factor in ac-
 quired [Dameshek & Levine] 641*
 ANEURYSM of abdominal aorta, survival for four years
 following dissecting [Wallwork] 451*
 ANGINA PECTORIS, treatment of, with testosterone pro-
 pionate [Lesser] 185*
 ANNUAL MEETING of Massachusetts Medical Society 583 - c
 ANTHELMINTICS, intestinal [Brown] 207 - mr
 ANTHRAX, epidemiologic, in Massachusetts [Tabershaw &
 Morris] 92*
 AORTA, abdominal, survival for four years following dis-
 secting aneurysm of [Wallwork] 451*
 APPENDICEAL abscess [Sowles & others] 724 - cr
 APPENDICITIS, acute 585 - MMS
 acute [Meigs & others] 834 - cr
 acute, in patients with common contagious diseases
 [Goodman & Silverman] 533*
 APPENDIX abscess [McKittrick & others] 401 - cr
 ARMY-NAVY "E" awarded to Parke, Davis and Company
 379 - misc
 awarded to Sharp and Dohme, Incorporated 298 - misc
 ARTHRITIS, rheumatoid, as cause of increased cerebrospinal-
 fluid protein [Ludwig & others] 306*
 rheumatoid, yardstick for [Bayles & Hall] 418*
 treatment (See Venom, cobra)
 ASTHMA, bronchial, occurrence of cor pulmonale in cases
 of [Schiller & others] 113*
 use of drugs in treatment of [Rackemann] 391 - mp
 ASTWOOD, E. B. (See Note) 298 - misc

B

- BACK to land 439 - c
 BENNETT, GRANVILLE A. (See Note) 807 - misc
 BIALOW, SOLOMON P. (See Deprivation of license) 558
 BIOLOGY history (See Montesquieu: biologist of the
 eighteenth century) [Dreyfus] 94*
 BIOPSY of prostate with silverman needle [Peirson &
 Nickerson] 675*
 BLACKOUT, pennant to identify vehicles in 592
 BLADDER neck obstruction [Mirabile] 751*
 BLINDNESS in premature baby 662 - MMS

- Blood derivatives, practical considerations in therapeutic
 use of [Newhouser & Lozner] 671*
 plasma 771
 plasma therapy (See Blood derivatives) [Newhouser &
 Lozner] 671*
 pressure values in relation to physical fitness in young
 men, resting-pulse and [Brouha & Heath] 473*
 BONE, fibrocystic disease [Albright & others] 100 - cr
 marrow changes [Warren] 111 - mr

CIVILIAN PUBLIC-HEALTH PROBLEMS IN WARTIME*

VLADO A. GETTING, M.D., DR.P.H.†

WORCESTER, MASSACHUSETTS

THE problem of civilian health is daily becoming more acute, although at present the health of the American people is as good as that of any other nation, if not better. This result has been achieved under peaceful conditions, but now we are at war. Here in Worcester, far removed from the battlefields and fighting, we are beginning to feel the pinch of war.

What are the problems of civilian health in Worcester? Is there going to be an increase in disease? Which diseases will become more prevalent? How can we safeguard the public health for the future? I propose to forecast the health status of the civilians in Worcester. We shall have an outbreak of some sort of illness, perhaps several, if the war lasts for years as is expected.

Perhaps we can best envisage the future of Worcester's health if we first review the occurrence of disease in previous wars. We can turn then to our experiences and review these in the light of war experience elsewhere.

MEDICAL HISTORY OF WARS

Former Wars

The history of wars prior to the twentieth century is characterized by accounts of great epidemics of bubonic plague, cholera, dysentery, malaria, smallpox, syphilis, typhoid fever and typhus fever. In twentieth-century warfare influenza, meningococcal meningitis and other respiratory diseases, venereal diseases and insect-borne diseases are the chief concern of military and civilian health authorities. Although the old-time diseases remain as possible dangers, they are controlled by continuous application of the principles of sanitation and epidemiology, and it is unlikely that they will again play a major role during war.

Under war conditions,¹ many of the safeguards of the health of both the military and civilian populations are abandoned. The crowding of large numbers of people in concentration camps, military establishments and air-raid shelters, or in an effort to keep warm, the primitive environmental sanitation and the lack of personal hygiene are all conducive to the spread of infectious diseases. The concentration and movement of armies and refugees, accompanied by the hardships of fatigue, general malnutrition and exposure and the lack of proper medical care provide the fuses for the explosion of widespread epidemics. More soldiers have been killed by infectious diseases than by bullets in all wars prior to the Franco-Prussian War of 1870, when the German Army experienced more deaths from battle than from disease. During the Russo-Japanese War of 1904, both sides suffered more from war casualties than from disease. In spite of the toll of influenza, the A.E.F. of 1917-1918 reported fewer deaths from sickness than from battle, although for the entire United States Army, at home and abroad, the deaths from disease were the more numerous of the two.

World War I

During and after World War I all infectious diseases except the common childhood communicable diseases were highly prevalent in eastern Europe.² There was an epidemic of typhus fever and relapsing fever throughout Russia, Poland and Serbia. Fortunately, these diseases did not spread into western Europe. Overshadowing all other outbreaks was the influenza pandemic, which caused an increased mortality from pneumonia. Meningococcal meningitis was epidemic, while dysentery, smallpox, tuberculosis and venereal diseases increased. Malaria, which had disappeared from most of Europe, returned to central, eastern and northern Europe to ravage the population.

*This and the two following papers were presented at a meeting of the Worcester District Medical Society, Worcester, September 9, 1942.
†Assistant in preventive medicine and epidemiology, Harvard Medical School and Harvard School of Public Health; commissioner of health, City of Worcester.

In the United States Army, respiratory diseases, venereal diseases, mumps, measles, dysentery and tuberculosis were the cause of about 95 per cent of absences from duty. Influenza, tuberculosis, measles and meningococcal meningitis were the leading causes of death. A most noteworthy fact is that the Army in the continental United States had generally higher rates for admission and days lost from duty on account of infectious diseases than did the A.E.F. Likewise, the Navy suffered a higher incidence of communicable diseases in training camps than on shipboard. The explanation of this phenomenon is that the Army and Navy personnel in this country were newly organized and therefore had a lower group resistance to infectious diseases; secondly, they were more exposed to infections from civilian populations than were the troops in Europe. Conversely, the danger of spread of infection from soldiers and sailors to civilians was enhanced in the United States.

World War II

In the present war, influenza, meningococcal meningitis and tuberculosis, as well as paratyphoid fever and bacillary dysentery, are again showing an increased incidence in the civilian population, both on the Continent and in the British Isles. Typhus fever and bacillary dysentery are of epidemic proportions in eastern Europe, and typhus will no doubt achieve high proportions during the coming winter. In Great Britain, the evacuation of school children did not result in an expected increase in the common communicable diseases, but, malnutrition, fatigue and lack of adequate shelter are the principal causes of the increase of illness in continental Europe. The hazards of infection have been intensified by crowding in bomb shelters. Scabies, impetigo and lice infestation are acute problems.

WORCESTER'S HEALTH PROBLEMS

As in modern warfare, so in the modern epidemiologic control of infectious diseases the maneuvers and strategy of the past do not offer a formula for success. Nevertheless an appreciation of former problems and of the experiences of the present war in Europe, together with the application of newer knowledge, may facilitate the control of infectious diseases in America. Undoubtedly the changed character of the leading infectious diseases of war and the partial limitation of outbreaks of classic war diseases may be considered the most encouraging results of the present-day epidemiologic control.

Industrial Accidents

The control of infectious diseases in Worcester is a joint responsibility of the medical profession

and the Health Department. Infectious diseases, however, are not the only problems with which we are faced today. With the increased rationing of food, which is apparently on its way, deficiency diseases of various types may become prevalent. With the employment of inexperienced laborers and of women, older men and the partially crippled in the war industries of the city, with overtime and the use of old machinery, unprotected by safeguards and with the crowding of machinery on a relatively small floor space in the rush of production, industrial accidents are bound to increase in number and severity. It is an accepted fact that crowded home conditions and worry and discomfort outside the workshop are responsible in large measure for many of the accidents that occur in industry. The roles of the physician, the health officer and the safety engineer are paramount. The United States Public Health Service³ has been most active in pointing out the hazards of industry and in developing methods for the conservation of the health of the war worker.

Malnutrition

Malnutrition has always been present in the United States.⁴ Surveys⁵ have revealed a surprisingly high incidence of nutritional deficiencies. The people of Worcester are better nourished than those in many parts of the country, but with rationing and food shortages, deficiencies are bound to occur. The employment in industry of both parents may result in nutritional disturbances among children. In an attempt to minimize malnutrition, the Worcester Health Department has secured the services of a nutritionist, lent to us by the Southern Worcester County Health Association.

Infectious Diseases

The control of infectious diseases is an ever-present problem. The health of the civilian population is vital and without it there cannot be victory. For some diseases we have adequate control measures, and the incidence of these has been steadily decreasing (Table 1).

Typhoid fever. Typhoid fever has decreased from a peak of 292 cases in 1909, when Worcester had a population under 150,000, to less than 10 cases a year since 1937. This decrease is due to proper control over water supplies, sewage disposal and food handling. Nearly all the recent cases are due to carriers or are secondary to unrecognized cases. We have had 7 cases in 1942. Three of these were in the same family; one was probably primary, with the other two patients secondarily infected. Three other cases occurred in a boardinghouse and were caused by a carrier who

helped prepare the food Unless there is a breakdown in our sanitation from bombing or because of mass evacuation, we do not expect any increase in typhoid fever

Other food borne diseases, however, may increase unless stricter measures are adopted in the sanitation of food handling establishments Small

four years Some of the decrease during the past ten years may be due to the experimental immunization conducted with the co operation of the Massachusetts Department of Public Health This program has now been abandoned owing to the unavailability of the immunizing material The last outbreak occurred in 1938 Since the incidence

§Made reportable in 1907

food borne outbreaks have been frequent this year These are indications of things to come The Health Department is preparing regulations for the proper handling of food and the proper sanitation of food handling establishments

Diphtheria Diphtheria is another disease for which we have adequate control measures Immunization was started in Worcester in 1923 and the number of cases has rapidly dropped There has not been a death from diphtheria here for all most three years However, the disease has been increasing in Massachusetts during the past two years, and an outbreak, characterized by sporadic cases, is likely to occur

Every child over six months of age⁶ should be immunized with three doses of fluid toxoid at intervals of three weeks or two doses of alum precipitated toxoid at a month's interval One dose of the latter is not adequate⁷ Combined preparations of alum precipitated toxoid and Sauer's⁸ or Kendrick's⁹ whooping cough vaccine are available and are efficient Unless most of the children are immunized there may be a reappearance of diphtheria in epidemic form in Worcester and Worcester County The Health Department is re-immunizing with 0.5 cc of fluid toxoid all children through the first four grades who were immunized more than three years ago This procedure is based on studies¹⁰ which have demonstrated that there is a gradual loss of diphtheria antitoxin titer with time

Scarlet fever Scarlet fever has occurred in Worcester in irregular outbreaks every three or

four years Some of the decrease during the past ten years may be due to the experimental immunization conducted with the co operation of the Massachusetts Department of Public Health This program has now been abandoned owing to the unavailability of the immunizing material The last outbreak occurred in 1938 Since the incidence

of scarlet fever toward the end of 1941 was high, as it was at the beginning of 1942, and since the outbreaks are three or four years apart, we should be on our guard for an increase in scarlet fever during the coming winter, with a peak in the spring of 1943

Measles Measles is another disease in which we have no specific control measures Its cyclic outbreaks are more regular than those of the other communicable diseases Epidemics have occurred in Worcester almost every three years The last outbreak was in 1940 In 1941 measles was on the down grade, and this year we are apparently in the trough of the wave In 1943 we should therefore expect an epidemic of measles Sometimes these outbreaks may be delayed a year but either 1943 or 1944 will be marked by one

Tuberculosis Although tuberculosis has been rapidly decreasing, owing principally to the hospitalization of cases and the education of the public, an increase in this disease is probable So far in 1942 we have had an increased number of cases Many of these are among selectees who have been rejected because of possible pulmonary lesions These men are re-examined and re-examined If the diagnosis is confirmed the entire family is checked for possible disease Crowded living conditions long hours of work and malnutrition may result in an increased incidence of tuberculosis

Whooping cough At the present time we are experiencing a severe epidemic, but one that is not unduly alarming Unfortunately our control measures against this disease are not yet fully developed

We are experiencing a most unusual incidence of whooping cough, higher than at any time in the history of Worcester, and we have every reason to believe that this disease will continue in epidemic proportions for many months. Ordinarily whooping cough, like other respiratory diseases, has a peak in late winter and early spring. This year the disease has continued at an increased incidence during the summer. With the increase in respiratory diseases in the fall, it is to be expected that whooping cough will continue to be epidemic. Isolation of cases and quarantine of contacts are not adequate control measures. Children, especially infants over six months and under three years of age, can be immunized either by Sauer's or Kendrick's whooping cough vaccine. Other preparations have not proved effective in the experience of epidemiologists and are therefore not recommended. Immunization should be carried out as soon as possible, since immunity takes several months to develop. Inoculation after exposure is not effective.

Influenza. There is no statistical or epidemiologic basis on which a pandemic of influenza can be predicted. From all the evidence at hand, it is impossible to say whether there will be a worldwide pandemic during or following this war. But we have some comfort in the knowledge that if influenza does menace the world, the mortality, thanks to the sulfonamide drugs, will be much lower. Influenza is relatively mild; it is the complicating bacterial pneumonia that kills, and for this we are much better prepared than we were some twenty years ago. Antipneumococcus serums and the sulfonamides will save many lives.

Other diseases. Time does not permit an analysis of other diseases. I should, however, like to point out that meningococcal meningitis has been increasing in Massachusetts during the past two years, and that we may expect to see an outbreak of this disease characterized by sporadic cases widely distributed. The use of sulfonamide drugs and antimeningococcus serum will probably greatly decrease the fatality rate.

SUMMARY

In brief review, we can expect in Worcester and in Massachusetts an increase in diseases due to malnutrition and an increase in industrial accidents. There will in all probability be an outbreak of scarlet fever in Worcester during the coming winter, with a peak in the spring of 1943. Measles can be expected to reach epidemic proportions in the winter of 1943-1944. Pulmonary tuberculosis is increasing, and the longer the war lasts the greater will be the increase. At the present time we are experiencing a severe outbreak of whooping cough in Worcester. There is also an increase in diphtheria and meningococcal meningitis in Massachusetts; sporadic cases and minor local outbreaks of both these diseases are probable.

Typhoid fever will not increase unless there is a break in sanitation. Other food-borne diseases must be controlled by stricter measures. Physicians must co-operate in the control of all these diseases by keeping their patients at optimal health. This means regular physical examinations, correction of defects, good nutrition and adequate immunization of children against smallpox, diphtheria and whooping cough.

HOSPITALS AND THE WAR*

CHARLES F. WILINSKY, MD†

BOSTON

MUCH has been said and a good deal written on the influence of the war on hospitals and hospital standards. In order that we may truly appreciate the significant roles which hospitals play in the life of a community, a brief picture of hospital evolution in the United States seems appropriate.

Hospitals, so aptly described as the workshops of the medical profession, have evolved in the comparatively short time of less than two thirds of a century from a total of approximately 150 hospitals with less than 30,000 beds to their present imposing size of over 6500 hospitals with more than 1,250,000 beds. Approximately \$4,000,000,000 represents the investment in the hospitals of America. More than 1,000,000 people are annually employed in these institutions, and over 12,000,000 people were hospitalized in the United States in 1941. What is the basic cause for this tremendous growth of the hospital system? The answer is found in the fact that the American public has increasingly recognized the advantages of the treatment of illness within hospital walls. Group judgment, availability of technical personnel, expensive and varied equipment including laboratories, x-ray units and so forth, all play their part in accurate diagnosis and scientific care. The average hospital stay has been tremendously shortened, the duration of illness lessened, and the wage earner restored to his job at an earlier moment, this representing an economic benefit of inestimable importance to the individual and the community.

As medicine has progressed, hospitals have contributed to its development in many ways. Normally the hospital concerns itself with the care of the patient, the training of personnel, the furtherance in varying degree of medical research and the teaching of people for more healthful living. To these fundamental services the war has added additional responsibilities. These include facilities in the event of enemy penetration, for the protection of patients, personnel and plant, the care of the injured and the evacuation of patients. These normal as well as abnormal functions represent a staggering load which is complicated materially at present by the enormous and constantly increasing shortage of personnel.

The personnel includes both the professional and the nonprofessional groups. Among the former are physicians, including interns and residents, nurses, laboratory personnel, dietitians, pharmacists and so forth. In the latter group are included everyone engaged in what we term the nonprofessional activities. Hospitals cannot compete with private industry. Many hospitals are dependent on private philanthropy, in order that essential free services may be rendered to those unable to meet the cost of hospital care. Industry is logically organized for profit. Hospitals, therefore, must normally employ those willing to work for what may be termed the lesser wage. The great demand in industry for labor, in all its forms, has depleted the hospitals of clerical workers, maids, waitresses, porters, scrubwomen, laundry workers, maintenance men and others and has indeed imposed great hardships on them.

Mention must also be made of the rising cost of supplies, as well as their quite frequent scarcity.

What are we going to do about it? This is a challenge that must be met. Hospitals must continue to function, and hospital care must continue to be given. We must not lower the standards, which are important for the preservation of life. We must continue to provide essential equipment and supplies. Judgment in its keenest form, however, will have to be exercised. The use of substitutes and relatively simple methods and procedures will be justified when the patients' welfare is not sacrificed. The critically ill must have priority and there must be a rationing, so to speak, of doctors, patients and hospital beds when that appears necessary.

We must curtail whenever possible. As an example, the laboratory and the x-ray should be limited to essential needs, and not used with the repetitious freedom of the past. Volunteers must supplement the efforts of the diminished ranks of paid personnel. The public must become educated to be less exacting, less demanding, more patient and more tolerant. They must be educated, for example, to go to their physicians for check ups and to hospitals only for the type of illness requiring hospitalization. They must be educated to require special nursing only when truly indicated, and to leave the depleted nursing personnel for the seriously ill. We must teach them to realize that everything is being done and will be done for their necessary care. Impatience with nurses

*An abstract of a paper presented at a meeting of the Worcester District Medical Society, Worcester, September 9, 1947.

†Lecturer on public health at Massachusetts Institute of Technology, executive director, Technical Hospital Department, Commissioner of Health, City of Boston.

We are experiencing a most unusual incidence of whooping cough, higher than at any time in the history of Worcester, and we have every reason to believe that this disease will continue in epidemic proportions for many months. Ordinarily whooping cough, like other respiratory diseases, has a peak in late winter and early spring. This year the disease has continued at an increased incidence during the summer. With the increase in respiratory diseases in the fall, it is to be expected that whooping cough will continue to be epidemic. Isolation of cases and quarantine of contacts are not adequate control measures. Children, especially infants over six months and under three years of age, can be immunized either by Sauer's or Kendrick's whooping cough vaccine. Other preparations have not proved effective in the experience of epidemiologists and are therefore not recommended. Immunization should be carried out as soon as possible, since immunity takes several months to develop. Inoculation after exposure is not effective.

Influenza. There is no statistical or epidemiologic basis on which a pandemic of influenza can be predicted. From all the evidence at hand, it is impossible to say whether there will be a worldwide pandemic during or following this war. But we have some comfort in the knowledge that if influenza does menace the world, the mortality, thanks to the sulfonamide drugs, will be much lower. Influenza is relatively mild; it is the complicating bacterial pneumonia that kills, and for this we are much better prepared than we were some twenty years ago. Antipneumococcus serums and the sulfonamides will save many lives.

Other diseases. Time does not permit an analysis of other diseases. I should, however, like to point out that meningococcal meningitis has been increasing in Massachusetts during the past two years, and that we may expect to see an outbreak of this disease characterized by sporadic cases widely distributed. The use of sulfonamide drugs and antimeningococcus serum will probably greatly decrease the fatality rate.

SUMMARY

In brief review, we can expect in Worcester and in Massachusetts an increase in diseases due to malnutrition and an increase in industrial accidents. There will in all probability be an outbreak of scarlet fever in Worcester during the coming winter, with a peak in the spring of 1943. Measles can be expected to reach epidemic proportions in the winter of 1943-1944. Pulmonary tuberculosis is increasing, and the longer the war lasts the greater will be the increase. At the present time we are experiencing a severe outbreak of whooping cough in Worcester. There is also an increase in diphtheria and meningococcal meningitis in Massachusetts; sporadic cases and minor local outbreaks of both these diseases are probable.

Typhoid fever will not increase unless there is a break in sanitation. Other food-borne diseases must be controlled by stricter measures. Physicians must co-operate in the control of all these diseases by keeping their patients at optimal health. This means regular physical examinations, correction of defects, good nutrition and adequate immunization of children against smallpox, diphtheria and whooping cough.

voted entirely to medicine; they carry on the hospital medical services and do consultant work. Their work will be further increased by a shortage of interns and hospital residents, and they will be required to spend more time in the hospitals. The number of surgeons will surely be depleted. All the specialties will have their problems, and the specialists will be so busy they cannot be expected to do other than their own work except in an emergency.

The chief problem we must meet is that of furnishing general medical care—the routine office work and housework. Of the 67 physicians in general practice, 8 are older men and of limited physical capacity. Of the group of surgeons, 8 do considerable general work, as do 5 obstetricians, giving, with the 20 internists, 92 men to do general medical work for 200,000 people. We can expect that the number will be further depleted by military service, illness and other factors, and furthermore, we shall not have the annual supply of young men starting to practice in Worcester.

Approximately 50 per cent of the house calls were made by men in the group that has gone into military service. These figures indicate a shortage of medical service quantitatively analogous to the shortage of gasoline. The question arises what can be done about it. One obvious answer is to let each physician handle his own problem in his own way and hope for the best. The other solution is some sort of co-operative planning. If the supply of gasoline were substantially limited as it is, and it were left to each dealer to use his own judgment in distributing his supply, we should undoubtedly have great confusion, inequalities and public resentment and a demand for government intervention. The medical profession faces similar hazards. Medical service, however, cannot be rationed by coupons. We have to take care of the sick, we have to man our hospitals.

What can be done by doctors as a group, is a problem for our society to decide. The specialists can organize themselves and handle their own peculiar problems. For the problem of general medical care during the emergency, we should have some sort of study committee to make definite suggestions concerning how we can best use our resources and keep in constant touch with the medical situation.

We must have public co-operation. To do this we must have definite recommendations to make to the public that will be helpful and not confusing. Many suggestions have been made. It is obvious that the doctor's time must be conserved and house calls be kept at a minimum. The doctor's day is planned in the morning, and when

possible house calls should all be received by 8 a.m. Vague directions such as "Do not call the doctor except when necessary" are useless, but if we could give the public a few concise statements of symptoms that are urgent and of those that are not, it might be helpful. For instance, abdominal pain lasting more than a few hours is urgent. Pain in the chest and bloody sputum are important, as is abnormal bloody discharge from any part of the body. On the other hand, a head cold with general malaise is not an emergency. We might in a tactful way explain to the public that chronic symptoms, nervousness, fatigue and so forth should be investigated, but that this should be done at the convenience of the physician. The periodic health examination, desirable as it is, may have to be postponed. As a substitute for it we might urge prompt examination at the appearance of new symptoms.

Many persons working in industry are on shifts that make it impossible to see the physician in his regular office hours, and must often do so in the morning. Many practitioners spend a good part of their mornings in the hospitals, and it would be a convenience and timesaver if facilities could be furnished for doctors to receive private patients at the hospitals when necessary. Some physicians find it necessary to see office patients by appointment, and we might obtain public co-operation in this. On the other hand, these physicians will probably have to examine urgent cases between or after appointments.

The greatest problem will be to cover house calls, especially calls at odd hours, at night and in emergencies. Nothing will be more discouraging or panicky to the public than calling one doctor after another unsuccessfully, and nothing will do more to create a public demand for government intervention in medical practice. We should have some definite plan to present to the public for this situation.

Probably the best plan would be a medical bureau maintained by our society to handle such calls at all times. However, the expense and organization involved make this impractical. An alternative plan might be this: Our hospitals have experienced switchboard operators available day and night. If we could obtain the co-operation of the hospitals, we might have each hospital act as a center to cover emergency calls. There could be kept at each switchboard a list of physicians available for such calls, including not only members of the staff, but physicians in the neighborhood without hospital affiliations. The public could then be instructed that if they cannot obtain a doctor of their choice they are to call the nearest hospital, and that the operator will then

undertake to send a physician. When the operator obtained a physician she would check his name on the list so that he would not be called again until the rest of the list was covered. If she failed to obtain a doctor in a real emergency, she could offer to send a cab, or if necessary an ambulance, to bring the patient to the hospital for emergency treatment. Thus the inevitable criticism of a neglected emergency could be avoided. This list of physicians would be kept available to the doctors so that everyone would be encouraged to do his share. In this way the hospitals could do a considerable public service without undue inconvenience or expense.

Our facilities will be strained to the utmost this winter during the usual epidemic of respiratory infections. One of our members suggested that we might obtain the co-operation of the district and public-health nurses so that at the request of a physician a nurse might visit a patient and give a report of the temperature, pulse and respirations and the appearance of the throat and general symptoms, and administer simple treatment at the physician's direction. This, of course, would have to be followed up either by a visit of the physician or by a satisfactory progress report by the nurse.

In this emergency the physician must conserve his own health and strength. It has been repeatedly shown in industry that fatigue is a leading cause of illness and accident, and no doubt fatigue makes the physician less effective and more liable to make mistakes. Every time a physician falls ill, the whole situation is aggravated. This means that physicians must have adequate rest and an occasional holiday.

* * *

In summary, we are faced with the problem of furnishing adequate medical service to the hospitals, industries and civilian populations of our communities in spite of greatly reduced personnel. In doing this we aim to preserve the high standards and best traditions of medical practice, and to do it so well that there will be no public demand for government intervention.

In order to accomplish this purpose, co-operative effort will be necessary, and we shall have to make the fullest use of our hospital facilities and the nursing profession. Every physician in civilian practice is as obligated to do his part as is the physician in the armed forces to fulfill his duties.

THE RELATION OF SEASON, WEIGHT AND PRICE TO THE VITAMIN C CONTENT OF ORANGES*

ARTHUR D. HOLMES, PH.D.,† JAMES A. PATCH, S.B.,‡ AND FRANCIS TRIPP, M.S.‡

STONEHAM, MASSACHUSETTS

ORANGES, principally in the form of juice, are extensively used by persons of all ages. Children, particularly infants, whose dietary usually lacks variety, are given orange juice as a source of vitamin C to prevent scurvy, and probably a large proportion of adults also ingest it, principally for its vitamin C content. It is impossible to determine accurately the amount of orange juice consumed in this country per year as an intentional source of vitamin C, but it is reported that the value of the 1941-1942 orange crop is in excess of \$117,000,000.¹ It has been estimated that oranges contribute about 624,080,000 gm. of vitamin C to the human dietary annually.² Thus they constitute one of the most important natural sources of this vitamin. In fact, if one assumes that the average daily requirement of vitamin C by 130,000,000 people in the United States is 75 mg. per person,

the orange crop would supply 17.5 per cent of the needed supply.² This being so, information concerning the vitamin C content of oranges is of definite interest to physicians, nutritionists and others responsible for the human dietary.

As shown in a study by Holmes, Pigott and Tripp,³ the vitamin C content of oranges purchased in this locality varied over wide limits and bore no close, consistent relation to the brand or the section of the country in which the fruit was grown. These results naturally prompted the present study of the relation of season, weight and cost to the vitamin C content of oranges purchased under normal trade conditions in this country.

SOURCE AND TYPE OF FRUIT

The oranges used in our study were purchased at a number of local retail stores, some of which were members of large chain-store organizations and some of which were under private-grocery-store management. Some purchases were also

*From the Research Laboratories, E. L. Patch Company.

†Formerly, director of research, E. L. Patch Company, now, research professor of chemistry, Massachusetts State College, Amherst

‡Research chemist, E. L. Patch Company

made from street-side hucksters. The oranges were purchased on a per-dozen basis, since it was assumed that the average family of urban and nearby suburban localities would presumably purchase in this quantity. An attempt was made to select fully ripe, plump, juicy fruit such as would be selected by the average thrifty buyer. Since oranges available in this locality are principally grown in California and Florida, an attempt was made to purchase approximately an equal number of samples of oranges from each of these localities. Unfortunately it was not possible to accomplish this at certain seasons of the year.

PROCEDURE

The oranges were assayed for their vitamin C content by the indophenoluraturation method. The juice was expressed from the fruit with a glass reamer. It was then strained through a light cotton 14 mesh strainer to remove the seeds and pulp. Care was exercised that the juice did not come in contact with metal at any time and that it did not remain exposed to the air after it was removed from the fruit.

The vitamin C determinations were made by combining 2 cc. of the strained juice with 20 cc. of 8 per cent acetic acid in a 50 cc Erlenmeyer flask. This mixture was titrated with the dye solution, which was added from a microburette until the final drop produced a faint pink end point that remained for at least thirty seconds. The dye solution was prepared by dissolving 0.1 gm. of sodium 2,6-dichlorobenzenoneindophenol in hot distilled water, made up to a volume of 200 cc and standardized against a solution containing 0.1 gm. of vitamin C (Cebione, Merck) in 100 cc of 8 per cent acetic acid, according to the method of Tripp, Satterfield and Holmes.¹

EXPERIMENTAL DATA

In order that the data accumulated in this study may have direct practical value to the reader, they are discussed in terms of daily human vitamin C requirements. Even a cursory survey of the literature reveals considerable disagreement regarding these requirements, but in the past it was generally accepted that 25 mg.⁷ or 30 mg.⁸ constitutes the minimal optimum requirement. Olliver,⁷ Hawley⁸ and Sweany et al.⁹ believe that 50 mg. represents the desired daily consumption. On the other hand, the American Medical Association (Smith¹⁰) holds that 50 mg. should probably be considered as the barely adequate rather than the optimal requirement, with considerably larger quantities desirable when economically possible. Van Eekelen,¹¹ Heinemann¹² and Sweany et al.⁹ recommend 60 mg. for the average adult, with larger quantities

for pregnant and lactating women. The requirements in pathologic conditions such as tuberculosis, nutritional anemia, scurvy, myeloid leukemia and Addison's disease may be many times that of the average normal young adult. For instance, Martin and Heise¹³ and Trautwein¹⁴ recommend from 150 to 200 mg. daily in the treatment of severe tuberculosis; Heilmeyer¹⁵ found that the daily administration of 300 to 600 mg. enhanced the therapeutic activity of iron in the treatment of secondary anemia; Abt and Farmer¹⁶ secured considerable depigmentation in Addison's disease by the oral administration of 450 mg. of vitamin C daily; Bastedo¹⁷ comments on the treatment of severe scurvy with 1500 mg. and Eufinger and Giechtgens¹⁸ restored to normal a patient with myeloid leukemia by the administration of 2000 mg. Although the population of the United States includes both normal persons and those suffering from various pathologic conditions, it has been assumed in this study that the recommendation of the Committee on Food and Nutrition of the National Research Council¹⁹ of 75 mg. per day constitutes a suitable human adult requirement.

Data concerning the influence of seasons on the vitamin C content of oranges were obtained by purchasing representative fruit in local retail markets in March, June, September and December, it was thought that this procedure was typical of orange purchases in this locality during the spring, summer, fall and winter seasons. An attempt was made at each season to secure representative fruit of different sizes, price levels and brands.

Table 1 contains data relative to the season, source, weight, cost and amount of juice per orange. It also reports the vitamin C content per 100 cc. of juice, the amount of juice required to produce 75 mg. of vitamin C and the cost of this amount on the basis of each orange assayed, except that the March assays were made on the composite juice of two to four oranges. For convenience in comparing the size of the orange with the other data, the samples have been arranged for each season in order of increasing weight.

The results obtained for the oranges assayed in March vary over wide limits and show average per-orange values of weight 206 gm., cost 28 cents per dozen, 77 cc. of juice, 52 mg. of vitamin C per 100 cc. of juice, and 144 cc. of juice required to yield 75 mg. of vitamin C at a cost of 48 cents. Similar values for June were 150 gm., 29 cents, 74 cc. of juice, 45 mg. of vitamin C, and 176 cc. of juice at a cost of 59 cents. In September the values were 160 gm., 27 cents, 76 cc. of juice, 39 mg. of vitamin C, and 196 cc. of juice at a cost of 59

undertake to send a physician. When the operator obtained a physician she would check his name on the list so that he would not be called again until the rest of the list was covered. Since oranges available in this locality are principally grown in California and Florida, an attempt was made to purchase approximately an equal number of samples of oranges from each of these localities. Unfortunately it was not possible to accomplish this at certain seasons of the year.

PROCEDURE

The oranges were assayed for their vitamin C content by the indophenoltitration method. The juice was expressed from the fruit with a glass reamer. It was then strained through a light cotton 14-mesh strainer to remove the seeds and pulp. Care was exercised that the juice did not come in contact with metal at any time and that it did not remain exposed to the air after it was removed from the fruit.

The vitamin C determinations were made by combining 2 cc. of the strained juice with 20 cc. of 8 per cent acetic acid in a 50-cc. Erlenmeyer flask. This mixture was titrated with the dye solution, which was added from a microburette until the final drop produced a faint-pink end point that remained for at least thirty seconds. The dye solution was prepared by dissolving 0.1 gm. of sodium 2,6-dichlorobenzeneindophenol in hot distilled water, made up to a volume of 200 cc. and standardized against a solution containing 0.1 gm. of vitamin C (Cebione, Merck) in 100 cc. of 8 per cent acetic acid, according to the method of Tripp, Satterfield and Holmes.⁴

EXPERIMENTAL DATA

In order that the data accumulated in this study may have direct practical value to the reader, they are discussed in terms of daily human vitamin C requirements. Even a cursory survey of the literature reveals considerable disagreement regarding these requirements, but in the past it was generally accepted that 25 mg.⁶ or 30 mg.⁸ constitutes the minimal optimum requirement. Olliver,⁷ Hawley⁸ and Sweany et al.⁹ believe that 50 mg. represents the desired daily consumption. On the other hand, the American Medical Association (Smith¹⁰) holds that 50 mg. should probably be considered as the barely adequate rather than the optimal requirement, with considerably larger quantities desirable when economically possible. Van Eekelen,¹¹ Heinemann¹² and Sweany et al.⁹ recommend 60 mg. for the average adult, with larger quantities

for pregnant and lactating women. The requirements in pathologic conditions such as tuberculosis, nutritional anemia, scurvy, myeloid leukemia and Addison's disease may be many times that of the average normal young adult. For instance, Martin and Heise¹³ and Trautwein¹⁴ recommend from 150 to 200 mg. daily in the treatment of severe tuberculosis; Heilmeyer¹⁵ found that the daily administration of 300 to 600 mg. enhanced the therapeutic activity of iron in the treatment of secondary anemia; Abt and Farmer¹⁶ secured considerable depigmentation in Addison's disease by the oral administration of 450 mg. of vitamin C daily; Bastedo¹⁷ comments on the treatment of severe scurvy with 1500 mg., and Eufinger and Gaehgens¹⁸ restored to normal a patient with myeloid leukemia by the administration of 2000 mg. Although the population of the United States includes both normal persons and those suffering from various pathologic conditions, it has been assumed in this study that the recommendation of the Committee on Food and Nutrition of the National Research Council¹⁹ of 75 mg. per day constitutes a suitable human adult requirement.

Data concerning the influence of seasons on the vitamin C content of oranges were obtained by purchasing representative fruit in local retail markets in March, June, September and December; it was thought that this procedure was typical of orange purchases in this locality during the spring, summer, fall and winter seasons. An attempt was made at each season to secure representative fruit of different sizes, price levels and brands.

Table 1 contains data relative to the season, source, weight, cost and amount of juice per orange. It also reports the vitamin C content per 100 cc. of juice, the amount of juice required to produce 75 mg. of vitamin C and the cost of this amount on the basis of each orange assayed, except that the March assays were made on the composite juice of two to four oranges. For convenience in comparing the size of the orange with the other data, the samples have been arranged for each season in order of increasing weight.

The results obtained for the oranges assayed in March vary over wide limits and show average per-orange values of weight 206 gm., cost 28 cents per dozen, 77 cc. of juice, 52 mg. of vitamin C per 100 cc. of juice, and 144 cc. of juice required to yield 75 mg. of vitamin C at a cost of 4.8 cents. Similar values for June were 150 gm., 29 cents, 74 cc. of juice, 45 mg. of vitamin C, and 176 cc. of juice at a cost of 5.9 cents. In September the values were 160 gm., 27 cents, 76 cc. of juice, 39 mg. of vitamin C, and 196 cc. of juice at a cost of 5.9

HEMORRHAGE FROM MECKEL'S DIVERTICULUM IN AN ADULT

Report of a Case

ABRAHAM SERVETNICK, M.D.* AND HOWARD G. NICHOLS, M.D.†

HAVERHILL, MASSACHUSETTS

MECKEL'S diverticulum occurs as a result of failure or complete obliteration of the omphalomesenteric duct. Its structure depends on the degree of obliteration that has taken place. It is usually situated on the antimesenteric side of the ileum, 30 to 90 cm. proximal to the ileocecal valve, but in rare cases it may occur at any other point in the gastrointestinal tract.¹ The tip of the diverticulum often lies free in the abdominal cavity. It may be attached to other viscera or to the abdominal wall, and rarely may be situated between the leaves of the mesentery.² Most diverticula are not over 10 cm. in length, but Tisdall³ has reported a diverticulum which was more than 100 cm. long.

Meckel's diverticulum occurs twice as often in males as in females,^{4, 5} and pathologic lesions involving it occur with greatest frequency in early childhood, but may do so at any age. The presence of a Meckel's diverticulum in approximately 2 per cent of the population^{1, 2, 6} and the fact that every third or fourth diverticulum becomes the seat of disease^{1, 4} emphasize the importance of this appendage in the differential diagnosis of abdominal disease.

Ulceration with hemorrhage or perforation; acute inflammation, various forms of obstruction and neoplasms are the important lesions with which this structure may be affected. Obstruction and inflammation are the pathologic entities most frequently encountered in adults, whereas hemorrhage is by far the commonest lesion in children.⁷

The presence of heterotopic tissue, which has been estimated to occur in 25 per cent of these diverticula,⁸ is significant, for it renders the latter particularly susceptible to ulceration. Gastric and jejunal mucosa and pancreatic tissue are the usual types of aberrant tissue found. Hudson and Koplik⁹ found gastric mucosa in 50 per cent of 23 cases of Meckel's diverticulum. Johnston and Renner¹⁰ reviewed 78 cases and found heterotopic tissue in 64, of which 50 presented evidence of ulceration. Moreover, intestinal hemorrhage occurred in 75 per cent of the cases containing the heterotopic cells. On the other hand, Brown and Pemberton¹¹ in 47 cases in which the diverticulum had been surgically removed, noted that bleeding had not occurred in any case and that the diverticulum contained gastric tissue in only 8 cases.

These studies suggest that the presence of gastric mucosa in a Meckel's diverticulum is deleterious and increases the likelihood of dangerous complications; for ulceration, when it does occur, usually develops at the junction of the ileal and heterotopic gastric mucosa, forming a marginal ulcer akin to a gastrojejunal ulcer. The ulcer is apparently the result of erosion of the intestinal mucosa by the secretions of the heterotopic gastric cells.¹⁰ The ulcer so formed usually penetrates the wall for a considerable depth. The variation in the site and extent of these ulcerations is dependent on whether only a part or the whole of the diverticulum is lined with gastric mucosa. The majority of the ulcers are situated at the bases of the diverticula. The accompanying diagram

FIGURE 1. Diagram Showing the Various Sites of Ulceration in 45 Cases in Which the Ulcer Sites Were Specified.

(Fig. 1) based on figures by Cobb¹² graphically portrays the relative incidence of the various ulcer sites.

The symptomatology of Meckel's diverticulum is primarily that of the underlying pathologic condition and falls into the following groups: inflammatory; obstructive; ulcerative, with and without perforation; and neoplastic. This study will be limited to a discussion of the ulcerative group.

In the cases of ulceration with perforation, the symptoms are those of peritoneal irritation: namely, abdominal pain, nausea, vomiting, tenderness and muscular rigidity. The resulting inflammatory processes are likely to be well localized.⁹

In ulceration without perforation, the cardinal symptom is hemorrhage. The bleeding may be

*Member of courtesy staff, Hale Hospital, Haverhill.

slight, periodic or intermittent over a long period of time, or it may be sudden and profuse, accompanied by the symptoms of severe blood loss. The character of the expelled blood is frequently of great diagnostic significance,¹³ for it is unlikely to be so dark or tarry as that from bleeding in the upper gastrointestinal tract or so bright red as that from hemorrhage of the colon.

Pain is a variable symptom but, if present, is usually located at the umbilicus. It may be periodic and related to meals but, unlike the pain of gastric or duodenal ulcer, is not relieved by food. Pain may be noted for the first time with or after hemorrhage and is then usually cramplike.

Tenderness and muscular rigidity are usually absent, but palpation frequently produces some feeling of abdominal discomfort.

The following case report of a Meckel's diverticulum with ulceration demonstrates the importance of the cardinal symptom of hemorrhage in unperforated cases. It is noted here in all its variations in a young man over a three-year period, with absence of any other symptoms.

CASE REPORT

A C, a 24-year-old telephone lineman, was seen for the first time in November, 1937, by one of us (A S). His chief symptom was bloody stools, which he had noted for several days, following what he believed was a "grippe" infection. There was no history of a gastrointestinal upset or of any symptoms that usually accompany disease of the gastrointestinal tract.

Physical examination was negative except for a soft systolic murmur heard at the apex of the heart and not transmitted, and a moderate anemia. The red-cell count was 3,400,000, with a hemoglobin of 65 per cent, and the white cell count 9000, with 65 per cent polymorphonuclears and 35 per cent lymphocytes. The blood smear was consistent with a microcytic anemia.

The rectum was cleansed by a saline irrigation, this was followed by a proctoscopic and sigmoidoscopic examination, which revealed no abnormality of the rectum or sigmoid other than a slight trickle of blood and the presence of small clots beyond the tip of the sigmoidoscope. Liquid rest was advised and a modified Sippy regime instituted. The stools gradually cleared of blood. The red cell count, which at first had dropped to 2,300,000 with a hemoglobin of 45 per cent, gradually rose so that at the end of 2 weeks it was 4,000,000, with a hemoglobin of 65 per cent. During this period there were no abnormal findings on repeated physical examination. A complete roentgen ray examination of the gastrointestinal tract showed no evidence of intrinsic disease.

In view of the negative findings, a diagnosis of either Meckel's diverticulum with ulceration and hemorrhage or a solitary bleeding polyp of the colon was entertained. Further roentgen ray study was advised either to confirm or rule out these conditions, but was not accepted.

There were no further bleeding spells until August 16, 1939, when a moderate-sized bloody stool was observed, unaccompanied by any subjective symptoms. Physical examination again yielded negative results. The red-cell count was 4,500,000, with a hemoglobin of 75 per cent, and the white-cell count 7600, with a normal smear. The fol-

lowing morning the stool was normal except for a few streaks of blood coating the fecal mass. The patient consented to a re-examination of the colon by a contrast barium enema. This showed no abnormality. Further roentgen ray examination of the gastrointestinal tract with special study of the small bowel was again advised, but was declined.

In view of the repeated intestinal hemorrhages with a lack of any other symptoms, the repeated absence of physical findings and the negative results obtained from blood studies and roentgen ray examination, an exploratory laprotomy seemed justifiable. This was advised, but the patient refused operation. He continued his bland diet of six meals a day, and in addition took 50 mg of vitamin C three times a day. Small amounts of blood were noted at times in the stool, but the patient continued at his work.

On the morning of October 2, 1940, the patient noted a small bloody stool, but went to his work as usual. Later, while at work, he suddenly felt weak and dizzy. Although these sensations lasted but a short time, he decided not to continue his work and drove a truck 9 miles to the company's garage. During the journey the weakness and dizziness recurred, accompanied by rectal incontinence. He was able to reach the garage and, without assistance, drove another 7 miles to his home. He was seen shortly afterward by one of us (A S) lying on a divan, his trousers and shoes covered with a dark, foul smelling, bloody discharge. The temperature was 97.6°F, the pulse 84, and the blood pressure 132/90. The patient's color was good, and there was no pain or distress. No further bowel movements occurred until late that night, when the patient again felt weak, perspired freely and had two large, dark, foul smelling, bloody movements. Examination showed a pale, perspiring individual whose pulse was weak, with a rate of 60, the blood pressure 86/60. One fourth gram of morphine sulfate was administered subcutaneously, and the patient was transported to the hospital.

On arrival he appeared somewhat better; his pulse rate was 96 and of good quality, and he complained of thirst. The following morning his condition was unchanged, the pulse was 96 and of good quality, and the blood pressure was 114/70. The red cell count was 3,400,000, with a hemoglobin of 50 per cent, and the white-cell count 19,000, with a normal differential. There were no recurrences of bloody stools during the next 36 hours.

During the afternoon of the 2nd hospital day there was a recurrence of weakness, accompanied by perspiration, slowing of the pulse rate and dropping of the blood pressure, with a free rectal discharge of dark, foul smelling blood. Morphine was immediately administered and a transfusion of 500 cc. of citrated blood was given, followed by a continuous intravenous infusion of 5 per cent glucose in physiologic saline solution. As a result of these measures an improvement was noted. The following morning, although no recurrence of bleeding had taken place, the patient appeared much paler and the red-cell count was 1,200,000, with a hemoglobin of 18 per cent.

One of us (H. G. N.) saw the patient in consultation. Since active bleeding had apparently ceased, it was decided to resort to daily blood transfusions in the hope of getting the red-cell count up to at least 3,000,000 before operation, but to operate immediately in the event of a recurrence of bleeding. This course was pursued. A daily transfusion of 500 cc. of citrated blood was given. There were no recurrences of bleeding and the red cell count

Report of a Case

ABRAHAM SERVEINICK, M.D.* AND HOWARD G. NICHOLS, M.D.*

HAVERHILL, MASSACHUSETTS

MECKEL'S diverticulum occurs as a result of failure or complete obliteration of the omphalomesenteric duct. Its structure depends on the degree of obliteration that has taken place. It is usually situated on the antimesenteric side of the ileum, 30 to 90 cm. proximal to the ileocecal valve, but in rare cases it may occur at any other point in the gastrointestinal tract.¹ The tip of the diverticulum often lies free in the abdominal cavity. It may be attached to other viscera or to the abdominal wall, and rarely may be situated between the leaves of the mesentery.² Most diverticula are not over 10 cm. in length, but Tisdall³ has reported a diverticulum which was more than 100 cm. long.

Meckel's diverticulum occurs twice as often in males as in females,^{4,5} and pathologic lesions involving it occur with greatest frequency in early childhood, but may do so at any age. The presence of a Meckel's diverticulum in approximately 2 per cent of the population^{1,2,6} and the fact that every third or fourth diverticulum becomes the seat of disease^{1,4} emphasize the importance of this appendage in the differential diagnosis of abdominal disease.

Ulceration with hemorrhage or perforation; acute inflammation, various forms of obstruction and neoplasms are the important lesions with which this structure may be affected. Obstruction and inflammation are the pathologic entities most frequently encountered in adults, whereas hemorrhage is by far the commonest lesion in children.⁷

The presence of heterotopic tissue, which has been estimated to occur in 25 per cent of these diverticula,⁸ is significant, for it renders the latter particularly susceptible to ulceration. Gastric and jejunal mucosa and pancreatic tissue are the usual types of aberrant tissue found. Hudson and Koplik⁹ found gastric mucosa in 50 per cent of 23 cases of Meckel's diverticulum. Johnston and Renner¹⁰ reviewed 78 cases and found heterotopic tissue in 64, of which 50 presented evidence of ulceration. Moreover, intestinal hemorrhage occurred in 75 per cent of the cases containing the heterotopic cells. On the other hand, Brown and Pemberton¹¹ in 47 cases in which the diverticulum had been surgically removed, noted that bleeding had not occurred in any case and that the diverticulum contained gastric tissue in only 8 cases.

These studies suggest that the presence of gastric mucosa in a Meckel's diverticulum is deleterious and increases the likelihood of dangerous complications; for ulceration, when it does occur, usually develops at the junction of the ileal and heterotopic gastric mucosa, forming a marginal ulcer akin to a gastrojejunal ulcer. The ulcer is apparently the result of erosion of the intestinal mucosa by the secretions of the heterotopic gastric cells.¹⁰ The ulcer so formed usually penetrates the wall for a considerable depth. The variation in the site and extent of these ulcerations is dependent on whether only a part or the whole of the diverticulum is lined with gastric mucosa. The majority of the ulcers are situated at the bases of the diverticula. The accompanying diagram

FIGURE 1. Diagram Showing the Various Sites of Ulceration in 45 Cases in Which the Ulcer Sites Were Specified.

(Fig. 1) based on figures by Cobb¹² graphically portrays the relative incidence of the various ulcer sites.

The symptomatology of Meckel's diverticulum is primarily that of the underlying pathologic condition and falls into the following groups: inflammatory; obstructive; ulcerative, with and without perforation; and neoplastic. This study will be limited to a discussion of the ulcerative group.

In the cases of ulceration with perforation, the symptoms are those of peritoneal irritation: namely, abdominal pain, nausea, vomiting, tenderness and muscular rigidity. The resulting inflammatory processes are likely to be well localized.⁹

In ulceration without perforation, the cardinal symptom is hemorrhage. The bleeding may be

*Member of courtesy staff, Hile Hospital, Haverhill.

slight, periodic or intermittent over a long period of time, or it may be sudden and profuse, accompanied by the symptoms of severe blood loss. The character of the expelled blood is frequently of great diagnostic significance,¹³ for it is unlikely to be so dark or tarry as that from bleeding in the upper gastrointestinal tract or so bright red as that from hemorrhage of the colon.

Pain is a variable symptom but, if present, is usually located at the umbilicus. It may be periodic and related to meals but, unlike the pain of gastric or duodenal ulcer, is not relieved by food.⁴ Pain may be noted for the first time with or after hemorrhage and is then usually cramplike.

Tenderness and muscular rigidity are usually absent, but palpation frequently produces some feeling of abdominal discomfort.

The following case report of a Meckel's diverticulum with ulceration demonstrates the importance of the cardinal symptom of hemorrhage in unperforated cases. It is noted here in all its variations in a young man over a three-year period, with absence of any other symptoms.

CASE REPORT

A. C., a 24-year-old telephone lineman, was seen for the first time in November, 1937, by one of us (A. S.). His chief symptom was bloody stools, which he had noted for several days, following what he believed was a "grippe" infection. There was no history of a gastrointestinal upset or of any symptoms that usually accompany disease of the gastrointestinal tract.

Physical examination was negative except for a soft systolic murmur heard at the apex of the heart and not transmitted, and a moderate anemia. The red-cell count was 3,400,000, with a hemoglobin of 65 per cent, and the white cell count 9000, with 65 per cent polymorphonuclears and 35 per cent lymphocytes. The blood smear was consistent with a microcytic anemia.

The rectum was cleansed by a saline irrigation; this was followed by a proctoscopic and sigmoidoscopic examination, which revealed no abnormality of the rectum or sigmoid other than a slight trickle of blood and the presence of small clots beyond the tip of the sigmoidoscope. Bed rest was advised and a modified Sippy regime instituted. The stools gradually cleared of blood. The red-cell count, which at first had dropped to 2,300,000 with a hemoglobin of 45 per cent, gradually rose so that at the end of 2 weeks it was 4,000,000, with a hemoglobin of 65 per cent. During this period there were no abnormal findings on repeated physical examination. A complete roentgen-ray examination of the gastrointestinal tract showed no evidence of intrinsic disease.

In view of the negative findings, a diagnosis of either Meckel's diverticulum with ulceration and hemorrhage or a solitary bleeding polyp of the colon was entertained. Further roentgen-ray study was advised either to confirm or rule out these conditions, but was not accepted.

There were no further bleeding spells until August 16, 1938, when a moderate-sized bloody stool was observed, unaccompanied by any subjective symptoms. Physical examination again yielded negative results. The red-cell count was 4,500,000, with a hemoglobin of 75 per cent, and the white-cell count 7600, with a normal smear. The fol-

lowing morning the stool was normal except for a few streaks of blood coating the fecal mass. The patient consented to a reexamination of the colon by a contrast barium enema. This showed no abnormality. Further roentgen-ray examination of the gastrointestinal tract with special study of the small bowel was again advised, but was declined.

In view of the repeated intestinal hemorrhages with a lack of any other symptoms, the repeated absence of physical findings and the negative results obtained from blood studies and roentgen-ray examination, an exploratory laparotomy seemed justifiable. This was advised, but the patient refused operation. He continued his bland diet of six meals a day, and in addition took 50 mg of vitamin C three times a day. Small amounts of blood were noted at times in the stool, but the patient continued at his work.

On the morning of October 2, 1940, the patient noted a small bloody stool, but went to his work as usual. Later, while at work, he suddenly felt weak and dizzy. Although these sensations lasted but a short time, he decided not to continue his work and drove a truck 9 miles to the company's garage. During the journey the weakness and dizziness recurred, accompanied by rectal incontinence. He was able to reach the garage and, without assistance, drove another 7 miles to his home. He was seen shortly afterward by one of us (A. S.) lying on a divan, his trousers and shoes covered with a dark, foul-smelling, bloody discharge. The temperature was 97.6°F., the pulse 84, and the blood pressure 132/90. The patient's color was good, and there was no pain or distress. No further bowel movements occurred until late that night, when the patient again felt weak, perspired freely and had two large, dark, foul-smelling, bloody movements. Examination showed a pale, perspiring individual whose pulse was weak, with a rate of 60; the blood pressure 86/60. One fourth grain of morphine sulfate was administered subcutaneously, and the patient was transported to the hospital.

On arrival he appeared somewhat better; his pulse rate was 96 and of good quality, and he complained of thirst. The following morning his condition was unchanged; the pulse was 96 and of good quality, and the blood pressure was 114/70. The red-cell count was 3,400,000, with a hemoglobin of 50 per cent, and the white-cell count 19,000, with a normal differential. There were no recurrences of bloody stools during the next 36 hours.

During the afternoon of the 2nd hospital day there was a recurrence of weakness, accompanied by perspiration, slowing of the pulse rate and dropping of the blood pressure, with a free rectal discharge of dark, foul-smelling blood. Morphine was immediately administered and a transfusion of 500 cc. of citrated blood was given, followed by a continuous intravenous infusion of 5 per cent glucose in physiologic saline solution. As a result of these measures an improvement was noted. The following morning, although no recurrence of bleeding had taken place, the patient appeared much paler and the red-cell count was 1,200,000, with a hemoglobin of 18 per cent.

One of us (H. G. N.) saw the patient in consultation. Since acute bleeding had apparently ceased, it was decided to resort to daily blood transfusions in the hope of getting the red-cell count up to at least 3,000,000 before operation, but to operate immediately in the event of a recurrence of bleeding. This course was pursued. A daily transfusion of 500 cc. of citrated blood was given. There were no recurrences of bleeding and the red-cell count

EXPERIMENTAL STUDIES

Interesting reports have appeared describing the study of *Treponema pallidum* with the electron microscope. Wile, Picard and Kearny⁶ have found that some spirochetes are enclosed in a continuous envelope of unknown nature. Flagella were sometimes seen attached at various points along the sides of the organisms, but not at the ends. Curious knoblike structures were described, which were held to be integral parts of the organism because of their uniform shape and density. Morton and Anderson⁷ have published similar findings. These investigators also found that some of the granules or knoblike structures were apparently in various stages of separation from the spirochetes. In some organisms constrictions were observed that were interpreted as the possible beginnings of transverse division.

Studies on the relation of vitamin C (ascorbic acid) to arsenical sensitivity have been continued by numerous investigators. Delp and Weber⁸ studied plasma vitamin C levels in untreated syphilis, patients under routine antisyphilitic therapy and cases that had shown definite arsenical sensitivity. Vitamin C levels were found to be unaffected by routine therapy. It was impossible to predict sensitivity from plasma vitamin C levels. Improvement in arsenical dermatitis, brought about by treatment with vitamin C, seems to be due to a forced increase in the plasma vitamin C levels. Bundesen and his co-workers,⁹ following the finding that ascorbic acid inhibits the oxidation of the arsphenamine radical, patch-tested known sensitive patients with a mixture of vitamin C and neoarsphenamine. Of 38 patients who showed strongly positive patch-test reactions to neoarsphenamine alone, 32 exhibited negative patch-test reactions with the addition of vitamin C. Vitamin C plasma levels had no effect on the reactions. It was the belief of these workers that patients who showed a positive patch reaction to a mixture of 30 per cent neoarsphenamine and 10 per cent ascorbic acid could probably not be desensitized by means of vitamin C. It is to be hoped that this approach may be utilized to detect which patients can safely continue treatment, with the help of vitamin C, even though they have become sensitized to the arsphenamines. Cormia¹⁰ has reported on the clinical use of ascorbic acid in arsenical sensitivity. He found vitamin C beneficial in the treatment of arsenical dermatitis and useful in the prevention of further reactions.

SEROLOGY

A great deal of work is continuing in the attempt to eliminate so-called "false-positive" serologic errors. Cardon and Atlas¹¹ have called atten-

tion to their discovery that biologic false-positive serologic reactions were observed in 8 (23 per cent) of 34 cases of hyperproteinemia and hyperglobulinemia associated with a variety of conditions, such as chronic pyelonephritis, cirrhosis of the liver with alcoholism, otitis media with erysipelas, pneumonia, acute pyelonephritis, paraplegia and dehydration. This is compared with a normal incidence of 1 false-positive reaction in every 4000 normal persons. Where a false-positive reaction is suspected, it may be well to institute blood-protein studies; increase in either the total serum protein or the serum globulin or both, in the presence of an associated anticomplementary Wassermann reaction, is strongly suggestive of a biologic false-positive reaction.

Kahn¹² has modified his "verification" test for syphilis for the differentiation of specific and non-specific serologic reactions. This author has previously described a verification test based on a differential-temperature technic. The present modification of the test relies on the observation that specific and nonspecific reactions are affected differently by certain concentrations of sodium chloride. It is thought that this removes the limitations of the differential-temperature technic. Kahn states that the present method makes possible the typing of either precipitation or complement-fixation seropositive reactions on the basis of their specificity. Chargin and Rein¹³ report their failure to achieve anything like consistently satisfactory results with the use of Kahn's technic. It is hoped that the performance of the latter's new modification will be more uniformly applicable as a verification procedure.

An interesting study was carried out by Burney, Mays and Iskrant.¹⁴ Eleven apparently nonsyphilitic dementia praecox patients were inoculated with malaria and all subsequently had at least one positive serologic test for syphilis. Eight different serologic technics were employed, some being carried out by more than one laboratory. The Hinton test was the only one that showed no positive reactions; there were, however, three doubtful reactions. No positive or doubtful reactions to any of the tests were returned on the negative controls. The greatest proportion of positive reactions occurred fifteen to twenty-one days after the clinical onset of the malaria. With one exception the positivity did not extend over a period of longer than four weeks. This study again emphasizes the importance of ruling out malaria in regions where this disease is endemic before making a diagnosis of syphilis based on serologic reactions alone.

The present status of biologic false-positive serologic tests for syphilis is most adequately summed up in an editorial¹⁵ that seems a more valuable

statement of facts than any paper reviewed. It did not seem possible to abstract this short dissertation satisfactorily, but one statement seems well worth remembering: "The reactivity of normal human sera with flocculation antigens is usually only minimal in degree, requires refined techniques for its demonstration, and is usually not apparent in the diagnostic tests." For all practical purposes, this refutes the popular conception that many false-positive tests are being reported. When the editor quoted used the term "diagnostic tests" he referred to the standard laboratory procedures such as are relied on by the average practitioner. It is only in institutions where serologic research is carried on that the previously mentioned refinements are obtainable.

A serologic technic for the titration of minute traces of reagin has been described by Lund.¹⁶ This holds great possibilities for the solution of the false-positive problem. It may place the serology of syphilis on a quantitative scale that far exceeds the scope of standard tests.

In former years there was an oft-quoted belief that serologic tests for syphilis are not reliable during pregnancy. Many have long known, however, that this was a false impression. Kandler¹⁷ reports a serologic study of 10,354 pregnant women. Several serologic technics were employed, and it was found that the degree of sensitivity was higher than in nonpregnant women. The specificity of the tests was not impaired, as there were but 0.20 to 0.32 per cent nonspecific reactions. This should silence any further comment on the unreliability of serologic tests for syphilis in pregnancy.

CLINICAL PROBLEMS

Transfusion syphilis. In previous progress reports it has been brought out that citrated whole blood, after a few days' refrigeration, is suitable for transfusion without danger to the recipient, even though syphilitic donors may have been employed. Turner, Bauer and Kluth¹⁸ have now shown that desiccated blood serum is also safe under the same circumstances. Their work was carried out with the spirochetes of both syphilis and yaws, and rabbits were utilized as test animals. All the control animals developed syphilis. After freezing and drying, from six to sixty-five times the amount injected into controls produced no syphilis. Therefore *Treponema pallidum* is commonly killed by the process of freezing and desiccation, even when the method is such that the viability of many bacteria and viruses is retained. It would thus seem that the transfusion of desiccated blood serum or plasma is probably without risk regarding the transmission of syphilis or yaws,

even though the material is obtained from infected donors.

Accidental infection. Leifer¹⁹ reports the cases of two dentists who presented paronychia of the left index-finger nail fold. Both had epitrochlear and axillary adenopathy. The first case went unrecognized until secondary syphilis developed two months later. Profiting by this experience, the author then utilized his heightened index of suspicion and diagnosed the second case by dark-field examination when the chancre was only two weeks old.

Infectious relapse. Eighty cases of infectious relapse were reviewed by Kern.²⁰ About two thirds of these relapses occurred in the first year after the end of treatment, and 80 per cent within the first two years. Relapses were most frequent in patients whose treatment was begun in the primary stage. Suboptimal therapy was followed by the greatest number of early relapses, their frequency decreasing as the total of arsenical injections increased, as one might expect. Kern believes that irregularity of therapy is unimportant as compared with inadequate amounts of treatment. He observed, however, that irregularity accounted for 75 per cent of relapses occurring after the first twenty injections of arsenic. These findings emphasize what we have again and again stressed in these progress reports: namely, that continuous treatment in adequate dosage is essential for the cure of early syphilis.

Osseous syphilis. It is probably a common tendency to think of destructive bone changes as manifestations of late syphilis. Statistically this is justified, but a report by Reynolds and Wassermann²¹ emphasizes the occurrence of destructive osseous lesions in early syphilis. Fifteen cases of osteitis, osteoperiostitis and osteomyelitis have been reported from the Johns Hopkins Hospital. This is an incidence of 0.15 per cent in 10,000 cases of early syphilis. The writers gathered 15 more cases from the literature. The bones of the skull were involved most frequently; those of the sternoclavicular region were next in frequency. Pain and localized tumefaction were the commonest symptoms, but varied according to the degree of periostitis. Pain was worst at night, but some cases were completely asymptomatic. Lesions of the bone occasionally preceded, rather than followed, the secondary eruption. Early syphilitic lesions, even when destructive, responded to treatment with prompt healing, leaving no residual evidence of their existence. It is interesting to call to mind the peculiar stubbornness often encountered in osseous lesions late in the disease. The osteomyelitis of late syphilis is also likely to be a source of diagnostic confusion, simulating such other condi-

tions as sinusitis, metastatic carcinoma, Paget's disease, osteitis fibrosa cystica, as brought out by Alexander and Schoch.²² These authors advocate a therapeutic trial in all problematic bone lesions with positive serologic tests for syphilis, before radical therapy is instituted. This is excellent advice.

Cardiovascular syphilis. The early diagnosis of syphilitic aortitis has been the subject of many dissertations. Kampmeier, Glass and Fleming²³ believe that the clinical diagnosis of uncomplicated syphilitic aortitis is, for all practical purposes, impossible. A report by Boharas, Hollander and Goldsmith²⁴ supports the contention that a positive clinical diagnosis of early syphilitic aortitis is nearly impossible. After a comparison of three technics of radiologic measurement it was concluded that a reliable diagnosis could not be made before a wide dilatation of the aorta had occurred. These authors go so far as to assert that a positive diagnosis of cardiovascular syphilis can be made only in the presence of saccular aneurysms, of aortic regurgitation appearing for the first time in middle-aged syphilitic patients, or of a diffusely dilated aorta without aortic regurgitation or hypertension, past or present. The asymptomatic phase of syphilitic aortic insufficiency was studied by McDermott, Tompsett and Webster.²⁵ Aortic insufficiency without aneurysm was found in 91 (4.5 per cent) of 2018 patients. Half these patients denied any symptoms of cardiac insufficiency at the time of diagnosis. It was possible to follow 28 patients for more than two years; 2 died of heart disease and only 2 others developed symptoms. The aortic width as judged from roentgenograms and fluoroscopy was normal in 43 per cent of these patients. The authors believe that this condition is frequently present in clinically recognizable form for long periods of time before the development of symptoms, and that the prognosis concerning the average duration of life is better than is usually believed. Bruenn²⁶ has published a dissertation on syphilitic occlusion of the coronary arteries. He believes that this diagnosis when made in the absence of signs of aortic insufficiency is likely to be wrong. Pain is a symptom of coronary insufficiency, but can occur with syphilitic aortic insufficiency without the presence of narrowed coronary ostia. Electrocardiograms and x-ray studies are said to be of no aid in differentiating syphilitic aortic insufficiency, with or without syphilitic closure of the coronary ostia. Treatment is of little avail and arsenicals are to be avoided. The prognosis is poor; patients rarely survive three months after the onset of pain; and death usually occurs suddenly. The author also discusses syphilitic lesions of the heart muscle.

Ocular syphilis. The unwarranted fear of arsenical therapy felt by many ophthalmologists was dissipated at a conference of therapy at the Cornell University Medical College and New York Hospital,²⁷ where it was stated that adequate proof exists that arsenic has no deleterious effects on the eye. Lesions of syphilis in the eye, so far as fundamental pathologic changes are concerned, are the same as syphilitic lesions elsewhere and should respond to the same chemotherapeutic measures. Iritis, uveitis, iridorecurrences, optic atrophy, choroiditis, optic neuritis and interstitial keratitis were discussed. In large groups of patients with iritis treated with arsenic, none became blind, whereas in several comparable series of cases given inadequate arsenical therapy blindness resulted in 9 per cent of the patients. Iridorecurrences are of special importance, as it has been found that 20 per cent of these are accompanied by neurorecurrences. In a series of 250 cases of untreated optic atrophy 90 per cent of the patients became blind in three years. Statistics were quoted as indicating that with malarial therapy as few as 12 per cent need become blind. It was brought out that some cases of interstitial keratitis may have permanent incapacitating scars even after intensive routine treatment plus fever therapy, but that such scars can be approached by means of corneal grafting. The need of co-operation between ophthalmologists and syphilologists was prominently stressed. This is timely. A large part of the data on optic atrophy quoted by the Cornell group was taken from the work of Moore, Hahn, Woods and Sloan,²⁸ who have published an exhaustive study of 250 cases. These men thought it probable that the fundamental process in optic atrophy is the same in all types of neurosyphilis and becomes bilateral soon after the onset of symptoms. Their data suggested that it can be prevented by adequate routine therapy of early syphilis. This type of therapy with trivalent arsenic and bismuth is useless after the onset of optic atrophy. Fever therapy (malaria in this series) was held to be the only efficacious method of approach. If visual failure progresses in spite of fever, no other treatment is likely to be effective. Swift-Ellis therapy was found to be of only dubious value in an occasional patient, and probably should be abandoned. So much variation was found in the course of optic atrophy that could not be accounted for by differences in treatment alone that some other additional factor was believed to be of importance in determining the outcome. In studying the types of field defects, it was thought that prognosis is less favorable in the presence of central or paracentral scotomas. Assinder²⁹ has reviewed 6839 ophthalmologic cases, in which syphilis was suspected,

that came under his observation in a period of fifteen years. One thousand and fifteen patients were found to have varying degrees of positivity of the Wassermann reaction. This large group was broken down, and the various types of lesions are discussed.

Neurosyphilis. In the last several years a series of papers has been published as a result of a "co-operative clinical study" of syphilis in five major clinics. The last publication in this series is a study of symptomatic neurosyphilis by Kierland, O'Leary and Vandoren.¹⁰ An evaluation of the therapy of 2019 cases is presented, covering the six major types of neurosyphilis. Each case was observed for not less than two years. The three early types of neurosyphilis are meningal, meningo-vascular and vascular. The three later types are tabes, paresis and taboparesis. The types of therapy used are routine, intraspinal, Tryparsamide, malarial and artificial fever. It was found that negative serologic tests for syphilis in the presence of positive cerebrospinal fluids occurred most frequently in tabes (24 per cent) and least frequently in meningal syphilis (11 per cent). The greatest number of so-called "fixed" positive cerebrospinal fluids were found in paresis and taboparesis. Malarial therapy was found to be the most effective in obtaining clinical improvement and in preventing progression of the disease. Intraspinal therapy, however, appeared to be the most effective means of reversing positive cerebrospinal fluids. From this it is easy to deduce that some cases may require the employment of both these complementary methods of therapy. The studies of this co-operative clinical group have indeed been productive of much valuable and illuminating material.

Tabetic cord bladder. Continuing work previously quoted in these progress reports, Emmett and Beare³¹ have by this time studied 419 cases of tabes with symptoms referable to the urinary bladder (42.4 per cent of 987 tabetic patients). One hundred and eleven male patients were subjected to cystoscopic examination, and 61 of these (55 per cent) had definite obstruction of the vesical neck. Thirty-five were subjected to transurethral prostatic resection. In the majority of cases it was difficult to decide whether vesical dysfunction had been the result of primary neurogenic atony, obstruction of the vesical neck with secondary atony or a combination of the two. The results of transurethral resection were gratifying and incontinence was never produced by the operation itself. The data obtained from this study led the authors to conclude that fibrosis or contracture of the internal (vesical) sphincter, or obstruction in this area, produced by enlargement of the prostate gland, is most likely to be responsible for urinary retention and difficult micturition. In concluding

they state, "Any tabetic patient who has difficulty in voiding, incontinence (especially of the overflow variety), residual urine and some demonstrable obstruction of the vesical neck has an excellent chance of relief of symptoms by complete transurethral resection." The same problem was studied by Nesbit and Gordon,³² who also believe that the modern treatment of the autonomous neurogenic bladder should be directed at surgical relief of the outlet obstruction. Emphasis is laid on the fact that the internal sphincter shares in the hypertonicity of the bladder, through destruction of neurogenic control, and acts as an outlet obstruction. An early approach is advocated by means of transurethral sphincterotomy, which has yielded gratifying results in the hands of these investigators, particularly when undertaken before the bladder has decompensated. Obviously if prostatic obstruction is also present, it could be relieved at the same time. This urologic approach to a serious problem in the management of the cord bladder is one that has been most worth while, and these two groups of workers should be complimented.

Congenital syphilis. Interesting statistics have been published by Wile and Mundt³³ on 500 cases of congenital syphilis. Ninety-eight of these patients were under two years of age; the most striking feature in this group was the finding of positive spinal fluids in 9 (47 per cent) of 19 cases in which punctures were done. Thirty-eight per cent of these infants exhibited developmental bone stigmas. Thirty-three per cent had some adenopathy. Five deaths were attributed to syphilis. Four hundred and two cases were tardive (over two years old). Fifty-nine per cent of these patients had eye lesions, and 37 per cent of these exhibited defective vision. Thirty-one per cent showed Hutchinsonian teeth. Thirty-nine per cent had bone lesions (4 per cent were active). In 343 tardive cases in which spinal fluids were obtained, 27 per cent were positive; half these patients were completely free of signs or symptoms of neurosyphilis. It is to be hoped that these findings will serve to place more emphasis on the need for thorough study of every case of congenital syphilis. Since there should be a decrease in the incidence of congenital syphilis as control of this disease progresses, and since fewer frank congenital lesions are now observed than formerly, it becomes even more important to watch carefully for physical evidence of the disease.

Brauer and Blackstone³⁴ have reported on the dental aspects of congenital syphilis. They undertook their study to determine the relative incidence of dental stigmas in both deciduous and permanent dentition. In contrast to the generally held view that syphilis does not cause changes in

deciduous dentition, these authors found changes that they believed could be due to syphilis in the deciduous incisors of 6 (37 per cent) of sixteen cases. Some enamel hypoplasia was also found in the posterior teeth. Twenty-four (63 per cent) of 38 patients showed syphilitic changes in the permanent incisors and 14 (37 per cent) in the molars. These children had been treated by the usual methods. In a dental study published by Johnston, Anderson and McAlenney,³⁵ the most constant characteristic malformation found in a series of 39 cases was dwarfing of the entire tooth and lack of development of the premaxillary bone, with incisors, canines and first molars usually showing such changes. These authors were unable to demonstrate spirochetes in any of the dental tissues. They state that it is still undetermined whether the spirochete acts directly and specifically in the production of dental anomalies commonly associated with congenital syphilis.

Some very pertinent points are brought out in a survey by the Ingrahams and their co-workers.³⁶ This group approached the problem of congenital syphilis from the preventive standpoint in an attempt to improve the attendance of pregnant syphilitic women in their clinic. The point was made that by means of an ante-partum syphilitic clinic, conducted as part of an obstetric service, more regular attendance would be achieved than if pregnant syphilitic women merely comprised part of the patients received by a large general syphilis clinic. It was further held that when postnatal medical supervision of the infant is carried out in a special session of the pediatric clinic or as part of the routine in a large general syphilis clinic, the results are not so good as those where a "family syphilis clinic" is maintained. Such a family clinic, as carried out by the authors, cut the elapsed time between the first visit of the pregnant woman and the beginning of treatment by two to four weeks. It also created a 100 per cent increase in the number of syphilitic pregnant women receiving regular therapy. It was thought that the proper medical follow-up could be accomplished only by a pediatric division in the family syphilis clinic or through the attendance of a syphilologist in the pediatric clinic. Stress was laid on the importance of having the same experienced follow-up workers care for the mother during pregnancy and follow both mother and child after delivery on the two services (obstetrics and pediatrics), a special family clinic being still better. This is a most worth-while report, and it should be read in full by all clinic executives, social workers, and obstetricians and pediatricians who are connected with syphilis clinics.

THERAPY

No current review of syphilis would be complete without mention of the second edition of Moore's³⁷ book on treatment. All phases of therapy of the many types of syphilis and its complications are clearly, comprehensively and authoritatively covered. The work on massive therapy is objectively reviewed. The author is apparently not an advocate of the five-day drip method of intensive treatment. He states that this has no advantage over conventional methods from a public-health standpoint since infectious relapses have occurred in 12 per cent of the cases. It is pointed out that, in spite of the admitted shortening of the treatment, the results have been attained at the cost of an enormous increase in danger to the patient, as shown by a fourfold increase in fatalities and a two hundred and twenty-fivefold increase in the incidence of hemorrhagic encephalitis. In addition to two new chapters and complete revision of several others, many items are added, such as sections on infectious syphilis in relation to treatment, the oral use of bismuth, mechanical fever therapy, erythema of the ninth day and congenital neurovascular and cardiovascular syphilis. This book should be readily available in the libraries of all who treat syphilis.

A new compound, bismuth ethyl camphorate, which was brought out by Thurmon³⁸ a few years ago, has been further studied by the same author³⁹ from the standpoint of excretion. He found this drug to be an extremely valuable adjunct to the arsphenamines in the treatment of syphilis. When administered in 2-cc. doses at seven-day intervals, bismuth ethyl camphorate maintains the desired level of bismuth in the circulation for a sufficient period to fall within the accepted standards of therapeutic effectiveness. Alexander and Schoch⁴⁰ have published a paper on the use of this same drug in 26 patients with early syphilis in which they began treatment with it. Fourteen cases were primary and 12 were secondary. *Treponema pallidum* promptly disappeared from the surface of lesions after institution of treatment, and healing began after the second day. The low toxicity of the preparation was confirmed. There were a large number of serologic reverses, which speaks well for the therapeutic effectiveness of this drug.

With the advent and rapidly spreading use of the sulfonamide drugs, a fear arose in many minds that the concurrent administration of these compounds with various antisymphilitic remedies might lead to serious toxic complications. A number of papers have appeared that serve to dissolve this apprehension, but only one will be mentioned. Brunet, Shaw and Reinhardt⁴¹ have reported on

the treatment of 44 patients with both syphilis and gonorrhea. These patients each received an average of 63 gm. of sulfanilamide, 6 gm. of an intravenous arsenical (four different drugs) and 2.5 gm. of intramuscular bismuth. No increased incidence of reactions from any of the drugs employed was observed.

The massive arsenical therapy studies that have been conducted in recent years have increased apace. Mounting incidence of syphilis under war conditions has provided more and more material for this investigation. In the 1941 progress report mention was first made of the multiple-syringe technic as a modification of the five-day intravenous drip method. From the same source, Schoch and Alexander⁴² have made a further report. They treated 350 patients by this technic. Two hundred and eight patients were given 120 mg. of Mapharsen daily for ten days, and 142 were given smaller doses over a longer period. Of the 208 treated by the ten-day schedule, 103 were observed for a period of six to eighteen months, resulting in 77 per cent satisfactory results; 11 per cent are pending and 12 per cent were failures. The latter included 3 infectious relapses, 6 serologic relapses, 2 cases with positive cerebrospinal fluids and 1 case of periostitis. Three patients with hemorrhagic encephalitis were encountered, 1 of whom died. The authors considered this technic to compare favorably with the five-day drip method.

Numerous other reports on massive therapy have appeared from various sources, with results roughly paralleling those quoted in the 1941 progress report. A list of references for those interested in this field is appended.⁴³ In an attempt to correlate this work more carefully and develop a short but safe schedule of intensive therapy, and for purposes of orientation, a clinical study has been organized in twelve co-operating clinics, as reported by Eagle and Hogan.⁴⁴ These workers have been studying the problem for several years, both clinically and experimentally. Over 2000 rabbits were given intensive Mapharsen therapy on various schedules. Within broad limits the curative dose was largely independent of the period over which it was administered. Mapharsen by intravenous drip was consistently less effective than when administered by repeated injections over the same length of time. The total amount of arsenic injected without killing the animal increased directly with the time elapsed. It is therefore obvious that the margin of safety (therapeutic index) can be increased by prolonging the duration of treatment. In the twelve co-operating clinics that are now carrying out the clinical study mentioned, three schedules are being tried. All three employ the multiple-syringe technic and vary from four to

eight weeks in duration, with injections of intravenous arsenicals triweekly. Some of the patients are being given concomitant weekly injections of bismuth. The results to date are encouraging with respect to toxicity.

What seems undoubtedly the most authoritative and comprehensive summary of the massive therapy problem is an editorial by Moore,⁴⁵ which was probably written even later than the new chapter in the second edition of his book. The dangers of the five-day treatment are fully stressed, and this program is compared with the treatment schedule suggested by Eagle and Hogan in the preceding reference.

It must be understood that a period of one to three years or longer of carefully controlled study will be necessary before it can be shown that the multiple-syringe technic carries less immediate danger than the five day drip method, or that it would be equally effective on a short term basis. It should be strongly emphasized that massive therapy of early syphilis is still in the experimental stage and unsuitable for general adoption. This point has been stressed each year in these progress reports. The final evaluation of the above methods of therapy must wait many years in order to determine the incidence of late complications, especially cardiovascular syphilis and neurosyphilis. Intensive arsenical therapy by any schedule is so far applicable only to selected cases of early syphilis, and is wholly unsuitable for any stage of late syphilis.

What may eventually prove to be a more outstanding advance in therapy is the combined fever and chemotherapy studies being carried out by Simpson, Rose and Kendell.⁴⁶ For some years these workers have been engaged in the study of artificial-fever therapy, and their present reports are more encouraging than earlier publications. Patients have been evaluated not only from the clinical standpoint, but by follow-up with quantitative serologic studies. Treatment with artificial fever alone was found to be of little value in arresting the progress of early syphilis. The subsequent institution of chemotherapy, alone or combined with fever therapy, was followed by a prompt fall in the quantitative titer and by clinical improvement. Combined fever and chemotherapy given biweekly did not seem to be more effective than weekly administration. The course of fever therapy consisted of ten to twelve treatments combined with the injection of an arsenical preparation and a bismuth compound. Following the course of combined fever and chemotherapy, injections of arsenic and bismuth were continued concurrently for twenty additional weeks. Clinical or serologic relapse has not occurred in this group of patients

CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITALANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29011

PRESENTATION OF CASE

A fifty-six year-old author came to the hospital because of crampy abdominal pain, nausea and vomiting.

Beginning six months prior to admission he was often awakened because of crampy abdominal pain that was usually followed by nausea and at times by vomiting. During the day he usually felt better, but was bothered by "bloating," eructations and belching. An x-ray study one month later demonstrated "colitis." One month before entry he developed constipation and often passed large amounts of gas by rectum. These symptoms were particularly noticeable since, following the resection of a fistula in ano fifteen years previously, he had never been completely continent of feces and movements tended to be loose. Five days before admission he became very constipated and suffered with extreme abdominal cramps, and subsequently his abdomen became distended. His physician treated him with repeated enemas, and some relief followed expulsion of gas. Three days later he began to vomit a thin fluid, which did not contain blood or coffee grounds and did not have a fecal odor. He had never noted tarry, bloody or acholic stools and had never been jaundiced. During the three months prior to admission he lost 20 pounds. For many weeks he was accustomed to drink as much as a pint of rye whisky each day "to relieve nervousness and insomnia," but this was discontinued during the week prior to admission.

The family and past histories were noncontributory.

Physical examination revealed a very ill, dehydrated man who grunted with each breath. The mucous membranes were pale, dry and cracked. Examination of the heart and lungs was normal. Both diaphragms were elevated to the fourth rib anteriorly, and chest movements were limited. The abdomen was enormously distended and tympanic throughout; no tenderness or spasm was demonstrated, and no masses were felt. The peristaltic sounds were weak and almost absent. No masses were felt on rectal examination, and sphincter control was absent.

The blood pressure was 122 systolic, 80 diastolic. The temperature was 99.1°F., the pulse 94, and the respirations 21.

Examination of the blood revealed a hemoglobin of 10.5 gm., red-cell count of 3,060,000 and a white-cell count of 16,700. The urine was cloudy, amber and acid in reaction, had a specific gravity of 1.010 and gave a ++ test for albumin, a green sugar test and negative tests for diacetic acid, acetone and bile; the sediment contained only amorphous urates. On another examination it gave a + test for albumin and contained a rare red cell, 10 white cells and 4 epithelial cells per high-power field; the sugar test was negative. The blood Hinton test was negative. The serum nonprotein nitrogen was 122 mg. per 100 cc., the chloride 94.6 milliequiv. per liter, and the protein 4.9 gm. per 100 cc. The stool was guaiac negative.

A flat plate of the abdomen demonstrated considerable gas in the dilated stomach and in numerous loops of small bowel, and probably a small amount of gas in the nondilated ascending and transverse colon. There was a large area of calcification overlying the fifth lumbar vertebra.

Many unsuccessful attempts were made to pass a Miller-Abbott tube into the small bowel. Accordingly, after glucose and saline infusions and plasma transfusions, under novocain infiltration, the abdomen was entered through a small oblique incision just to the left of the rectus muscle in the left lower quadrant. The abdomen was explored with two fingers, and a hard mass was found approximately in the midline near the promontory of the sacrum. It was stony hard and was thought to represent the calcified mass of lymph nodes seen in the x-ray. A small tag of omentum presented into the wound and on this were numerous small gray areas suggesting fat necrosis. There was considerable straw-colored free fluid in the peritoneal cavity. A loop of small bowel was drawn into the wound, and a Witzel-type enterostomy was established. The biopsy of omentum showed fat necrosis.

Three days later, the patient seemed slightly improved. The distention was definitely reduced, and the respirations were slower and easier. Peristaltic sounds were more normal on the third hospital day. He was started on a course of intravenous sodium sulfadiazine, totaling 25 gm. in five days. On the sixth hospital day the liver edge was felt three fingerbreadths below the costal margin and seemed rough and uneven. At this time there was definite dullness and consolidation above the high diaphragm on the right side, with increased transmission of breath and voice sounds and occasional rales. The temperature was 99.8°F., the pulse 98, and the respirations 25. The decompression tube was draining a yellowish-brown fluid.

drained from the enterostomy opening. He died on the fortieth day after admission, which is exactly the right time for a patient to die with necrotizing pancreatitis. The patient that almost but does not quite survive pancreatitis is very apt to live just about six weeks.

This man's story is very confusing and it brings up a lot of interesting points. One may hazard a good many guesses about where the underlying pathologic process really was but the chance of being right, so far as I am concerned, is very remote. The patient could perfectly well have had an ileus without having either an intrinsic or extrinsic lesion in the bowel: that is, the ileus could have been on the basis of gastritis and alcoholism. However, he had lost 20 pounds in weight. This man was developing a disease that manifested itself as an acute picture when he came in but actually was an end result of something that had been going on for a period of nearly half a year, possibly longer. It is conceivable that he could have had a reactivation of his mesenteric adenitis. When I saw the first film and read the story, it occurred to me that possibly this was going to turn out to be a gallstone ileus, but I now believe that the film does not have the appearance of a gallstone in a loop of small bowel. One might consider that this was really just cirrhosis of the liver, and pin everything on that as a diagnosis, but there is very little evidence of that. The palpation of the liver, the size of the liver, the ileus and so forth, are compatible but I think such a diagnosis is rather farfetched. The patient could have had, I suppose, some chronic situation in the pancreas that might have led up to an acute episode of this sort, but it seems rather unlikely. It is certainly not the usual history for a man to have a warning six months prior to the time he comes down with pancreatitis, which usually comes out of a clear sky without any long prodromal history. One has to think of tuberculosis, as I mentioned earlier in the discussion, because there is some evidence of certain types of tuberculosis in his past history. I am not sure about the chest; I should suppose that Dr. Holmes would say it was clear so far as any chest lesion is concerned.

That brings us down to the possibility of a lesion in the small intestine of a carcinomatous nature, which might conceivably have been overlooked. It is possible that such a lesion in the small bowel might have been between the point of ileostomy and the portion of the ileum filled from the barium enema. I think that is the most likely diagnosis. The reason I think so is that it is the one area that could not be definitely ruled out by the surgeon and that could not be studied by the x-ray man, using contrast mediums. The next best possibility is some extrinsic neoplasm secondarily involving the

bowel. In this instance I assume that the liver was full of tumor and that is what was the matter with the liver, not cirrhosis.

DR. HOLMES: May I add a few points? In these films it does not look as if the liver conforms to the clinic interpretation. It is a little large but not abnormal in shape. The hepatic flexure is not displaced downward. I wonder if you put enough weight on the fluid in the left pleural space. There was some fluid there earlier, and later a considerable amount.

DR. ALLEN: The patient could have had carcinoma involving the diaphragm, or a primary lesion of the lung, if you choose. I am not worried about the chest picture. In carcinomatosis of the abdomen one often sees fluid in the chest, many times because the diaphragm is studded with carcinoma.

DR. FRANSEEN: The site of the ileostomy was chosen because at the time of the flat film the point of obstruction appeared to be in the ileocecal region and we wanted to reserve the right lower quadrant for the second operation.

DR. DWIGHT L. SISCOE: I followed this patient very closely outside the hospital. Dr. Allen included all diagnoses that we were interested in and considered some more too. There were a few points that Dr. Allen questioned. One was the alcohol. The alcohol made a much greater impression on our minds than the record here would suggest. The roentgenologist who first examined him was greatly impressed by the gastritis and the amount of alcohol consumed. In fact we received word that he had been using a quart a day instead of a pint. So the possibility of cirrhosis was very much in our minds. During the last few days of his life the patient ran a steady downhill course, and a few days before death one observer believed that he felt a mass in the right lower quadrant.

DR. FRANSEEN: The patient was scheduled for operation, but that morning had a large hemorrhage and the operation was called off. That was twenty-four hours before death.

CLINICAL DIAGNOSIS

Carcinoma of stomach?
Portal cirrhosis?

DR. ALLEN'S DIAGNOSIS

Carcinomatosis, involving the lower ileum.

ANATOMICAL DIAGNOSIS

Pancreatitis, hemorrhagic, subacute.
Fat necrosis, extensive.
Rupture of splenic artery and vein.
Erosion into duodenum, with massive gastrointestinal hemorrhage.

Chronic cholecystitis
 Cholelithiasis, with stone in ampulla of Vater.
 Tuberculous mesenteric adenitis, healed.
 Arteriosclerosis, moderate: aortic, coronary and renal

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: At autopsy innumerable foci of fat necrosis covered the peritoneal surfaces from the bottom of the pelvis to the inferior surface of the diaphragm. The entire pancreas had been destroyed, and the retroperitoneal tissues of the upper portion of the abdominal cavity were occupied by a huge blood-filled cavity with shaggy, necrotic walls. Into this cavity dangled the ends of the splenic vein and artery, neither of which was thrombosed. A spontaneous rupture had occurred into the posterior wall of the third portion of the duodenum, so the terminal event was evidently hemorrhage from the splenic vessels into the cavity and hence into the duodenum, filling the gastrointestinal tract with blood. It was interesting that both pleural cavities contained small amounts of clear straw colored fluid so the supposed chest tap must have penetrated into the retroperitoneal cavity. The extremely high diaphragm made this readily possible. The liver was at the upper limit of normal in size, weighing 1800 gm., and was not nodular or cirrhotic. It did show extensive acute central necrosis, which accounts for the terminal liver insufficiency.

This man had the classic setup for acute pancreatitis. There was a severe chronic cholecystitis with innumerable small stones. The prodromal symptoms that led Dr. Allen to trace the onset of his illness back at least six months may well, in retrospect, have been due to his gall bladder. There was likewise a small stone in the common duct partially imbedded in the mouth of the duct of Wirsung. There was thus a real possibility of reflux of bile into the pancreatic duct. It must be admitted, of course, that few cases of pancreatitis show a calculus in the appropriate location.

DR. ALLEN: The straw colored fluid, five days after the pancreatitis started, is the thing that bothered me. Do you believe that that is usual? We frequently do a paracentesis to make a differential diagnosis between pancreatitis and perforated ulcer, and things of that sort, and we rely on the character of the fluid to guide us.

DR. MALLORY: I should consider clear yellow fluid unusual too.

DR. ALLEN: The serum amylase determination, so far as I could tell from the record, was not done till the fifth or sixth day, so that it had to be thrown out as a guide. If that had been done

the first day I think it would have had more significance.

DR. JOSEPH C. AUB: Why does a patient with pancreatitis die on the fortieth day?

DR. ALLEN: It takes just about that long for the pancreas to become completely necrotic and erode a big vessel, usually the splenic artery.

DR. SISCOE: I am sorry Dr. McKittrick is not here to discuss this case, since he held out for the diagnosis of pancreatitis almost from the start. He believed that the intra-abdominal fat necrosis could be explained in no other way.

CASE 29012

PRESENTATION OF CASE

A fifty-year-old man entered the hospital complaining of marked ankle edema of three weeks' duration.

The patient was seen for the first time in the Out Patient Department six months before admission. He stated that about a year and a half previously he had caught cold and that a cough coincident with the illness had persisted and was accompanied by a run down feeling, generalized weakness and increasing exertional dyspnea. About five months later he noticed palpitation and swelling of the ankles, which gradually rose to the knees and scrotum; these persisted, and at the time of being seen he was compelled to sleep using two pillows and to urinate three or four times during the night; at no time had there been any pain, but there was some loss of weight. On examination the patient was emaciated and rather ill-looking, with increased respirations, slight cyanosis of the lips, venous distention in the neck and over the abdomen and edema of the lower legs and scrotum. The chest was deformed (no description noted), and although the heart was not enlarged to percussion, its rate was 100 with an occasional extrasystole and a diffuse apex beat. The examiner believed that he heard a soft systolic murmur and a questionable presystolic murmur at the apex. The blood pressure was 95 systolic, 60 diastolic. There were a few rales at the lung bases, and the liver was percussed four finger-breadths below the costal margin.

The urine was negative, and the blood showed a hemoglobin of 16.9 gm. and a normal smear. One sputum examination was negative for tubercle bacilli. The electrocardiogram showed a normal rhythm with a rate of 85 and a PR interval of 0.13 second. P₂ was prominent, and there was marked right-axis deviation; S₂ was prominent, and ST₂ and ST₃ slightly sagging; T₄ was low, with an absent R₄.

On x-ray examination the diaphragm was low and limited in motion on both sides, and the lung fields were very bright. Rather sharp linear mottled areas of increased density and numerous small and large blebs were visible in the upper lung fields. There was marked depression of the lower end of the sternum; the heart was not particularly abnormal.

The patient was sent home to bed on digitalis and a low-fluid and low-salt intake; mercurial diuretics were administered in the Out Patient Department. He visited the hospital each week, and although a curtailment of activity brought about some improvement, dyspnea, venous congestion, cyanosis, basal rales and peripheral edema were always present in varying severity.

The right border of the heart was percussed 2 cm. to the right of the sternal border, whereas the left border was within normal limits. The rhythm was normal, with an occasional premature beat. The sounds were distant, and it seemed to be the consensus that there was no presystolic murmur and that the systolic apical murmur was not always heard. The blood pressure varied from 115 to 90 systolic and from 90 to 60 diastolic; the pulse averaged 90. Four and a half months before entry an electrocardiographic recording with six chest leads showed a normal rhythm with a rate of 110. The P waves in all leads were inverted; QRS was multiphasic and almost isoelectric; S was of high voltage, being highest in Leads 3 and 4. R_1 was less than 0.5 mm. in all leads. T was inverted in Leads 1 and 2, low to flat in Lead 3 and upright in Leads 4, 5 and 6.

As time passed, cyanosis became a more prominent feature, although it was still possible for the patient to lie flat fairly comfortably. Also, he began to mention nocturnal dyspnea, cough and abdominal distention. Mercurial diuretics continued to increase renal output, but in later months this effect was nullified by prolonged periods of oliguria.

A little more than a month before entry the patient came to the Out Patient Department and was obviously much worse, with an increase in dyspnea, cyanosis, peripheral edema, basal rales, liver size and abdominal distention. Consequently he was sent to a nursing home, but returned later and was admitted to the hospital.

The family history was noncontributory. At twenty years of age the patient had gonorrhea. Twenty-five years before admission he had a sudden sharp precordial pain that occurred while at rest and was severe enough to preclude movement. He was taken to another hospital and told that he suffered from "pleurisy around the heart." Strapping gave great relief and convalescence was uneventful, pain being the only symptom.

On examination the patient was well developed, but emaciated and somewhat confused; he had a hacking cough, which produced frothy, yellow sputum. There was marked cyanosis of the fingers, lips and ears, which seemed out of all proportion to the dyspnea. In the upright position the neck veins were distended and pulsating. The chest showed a marked pigeon-breast deformity and a Harrison groove and because of this it was difficult to percuss the heart, although the right border seemed to be 2 cm. from the sternal margin, and the left border 8 cm. from the midline. The sounds were distant and regular, and a soft systolic murmur was present at the apex. The pulmonary second sound was greater than the aortic. There were percussion dullness, diminished breath sounds and tactile fremitus and moist rales over the lower half of each lung field, but above this, hyperresonance and bronchovesicular breathing. The abdomen was distended and tense, with an everted umbilicus and shifting dullness; the liver edge was three fingerbreadths below the costal margin in the midclavicular line. Pitting edema of the back, sacrum, scrotum and lower legs was present. Examination of the nervous system was negative except for some confusion concerning current events.

The blood pressure was 85 systolic, 65 diastolic. The temperature was 98°F., the pulse 100 and the respirations 30.

The urine was acid in reaction and showed a +++ test for albumin and a + test for bile; the sediment contained 5 to 10 red cells and many white cells per high-power field. Examination of the blood showed an average red-cell count of 5,880,000 with a hemoglobin of 21 gm., and a white-cell count of 7450 with 84 per cent polymorphonuclears. The hematocrit reading was 60 per cent, and the blood bicarbonate 27.2 milliequiv. per liter. The nonprotein nitrogen was 93.5 mg. per 100 cc., and a blood culture was negative.

An electrocardiographic recording showed a normal rhythm with a rate of 100 and a PR interval of 0.16 second. There was low voltage in all leads, with moderate right-axis deviation. T_1 was low, and T_2 and T_3 inverted; there was an elevated takeoff in ST_4 , and an absent R_4 .

The patient was given the usual supportive measures, but death occurred on the third hospital day, with no notable clinical incident in the interim.

DIFFERENTIAL DIAGNOSIS

DR. DONALD S. KING: A clinicopathological conference is like a game of contract bridge. You are dealt a hand. You sort your cards into four suits; history, physical examination, laboratory and x-ray.

You pick out the high cards, which you can depend on to take tricks. Then you try to find out what other players at the table, such as the roentgenologist and the cardiologist, may have to influence your estimate of the situation. And finally you bid everything that you think you can make.

Well let us look at the hand. The history is that of a man of fifty who at twenty-five had precordial pain, which was probably due to pleurisy and is not connected with the terminal illness. Two years before entry he had a cold followed by cough, weakness and exertional dyspnea. These early symptoms were probably pulmonary, not cardiac. Nineteen months previously there was ankle edema, and later, edema involving the scrotum and back, palpitation, orthopnea, nocturia and weight loss. Finally there were nocturnal dyspnea, abdominal distention and frothy, yellow sputum.

The signs were emaciation and a pigeon breast, rapid respirations, cyanosis, — at first slight but becoming marked and out of proportion to the dyspnea, — venous distention in the neck, an enlarged liver and shifting abdominal dullness. The heart examination showed a pulse of 90 to 100 with occasional premature beats. The right border is said to have been 2 cm. from the sternal margin, but in the face of a pigeon breast and emphysema I may be excused for being skeptical. The pulmonic second sound was greater than the aortic, there was a soft systolic murmur, the blood pressure was from 85 to 115 systolic and from 60 to 90 diastolic, and the lungs showed basal rales and, at the last examination, basal dullness with diminished breath sounds and tactile fremitus with hyperresonance above.

The blood showed a moderate degree of polycythemia with a hemoglobin elevated to 21 gm., a red-cell count of 5,800,000 and a hematocrit of 60 per cent. The urine was that of congestion, with albumin, a little bile, a few red cells and many white cells. The nonprotein nitrogen was 93.5 mg., probably a terminal condition, and the bicarbonate level was essentially normal.

The x-ray films showed generalized emphysema, as evidenced by the low flat diaphragm, both sides of which are said to have been limited in motion, and the bright lung fields. Besides there were many emphysematous blebs. There were also what are described as sharp linear mottled areas. I do not like the term "linear mottling" but we can look at the film later and get an idea of what is meant.

In general this is the complete picture of failure of the right side of the heart. With marked cyanosis, distention of the neck veins, enlarged liver, rales, edema and an increased pulmonic second

sound we can bid at least a little slam on that diagnosis.

But we must go farther and try to find the reason why the right heart failed. There are two possible classes of causes — cardiac and pulmonary. The cardiac conditions that may cause congestion of the pulmonary vascular bed and therefore strain on the right side of the heart leading to failure are two: failure of the left side of the heart, as in arteriosclerotic hypertension, and deformity of the mitral valve, usually with stenosis. The possible pulmonary conditions are likewise two: emphysematous changes, which lead to a narrowing of the vascular bed with resultant pulmonary hypertension, and primary changes in the pulmonary arteries themselves. And to continue one step farther, the possible changes in the pulmonary arteries are three: sclerosis, obliterative endarteritis (frequently referred to as Ayerza's disease) and thrombi or emboli.

For the sake of clarity I shall at this point jump to my major clinical conclusion concerning the choice among the six possible causes of right-sided heart failure. I maintain that there is no evidence of left-sided heart failure, of deformity of the mitral valve or of any other condition of the heart itself that would account for the right-sided failure. I am driven then to a diagnosis of chronic cor pulmonale with the primary difficulty in the lungs. Emphysema of marked degree is undoubtedly present, and there have been autopsies in this hospital where such emphysema was the only explanation for pulmonary hypertension and consequent right-sided failure. But we should go farther and try to dispose of the pulmonary vascular conditions that I said might be present.

In the face of emphysema it is unnecessary to postulate pulmonary arteriosclerosis, which it is impossible to prove in any case. Obliterative endarteritis is usually a disease of younger people, and the etiologic factors sometimes found, such as syphilis, rheumatic fever and chronic bronchial infection, are absent. We come then to the last of the possible pulmonary vascular changes — thrombosis or embolism. For some unexplainable reason I want to bring such changes into this picture; there are no symptoms of them, and unless the x-ray films show evidence, it seems to me that we should drop this cause from the list of possibilities.

There is much that we do not know about pulmonary hypertension and its causes. I remember only too well the case of a "black cardiac" given to me in one of these conferences; the patient had all the signs of right-sided failure with much more marked cyanosis than that in the present case, and yet at autopsy Dr. Mallory found almost no struc-

tural changes. If I remember correctly there was moderate sclerosis, but nothing else — no thrombi, not even any demonstrable narrowing of the lumens of the arteries or arterioles. So in the present case I shall, after x-ray conference, probably leave out thrombosis as unnecessary to explain the picture and as incapable of proof.

At this moment, without careful study of the x-ray films and the electrocardiograms, my clinical diagnosis is pulmonary emphysema with emphysematous blebs, probably with fibrosis, and chronic cor pulmonale with right-sided heart failure.

Now to the x-ray films and electrocardiograms to see what other factors they may introduce.

This is the x-ray film, and it is obvious that there are generalized emphysema and emphysematous blebs. The next question concerns the "mottling" in the upper lobes. Dr. Lingley, are the changes in this film consistent with pulmonary fibrosis?

DR. JAMES R. LINGLEY: There is marked emphysema, as described. The distribution of the density is more consistent with tuberculosis than with ordinary fibrosis. It is fibrosis, certainly, but tuberculous fibrosis or fibroid phthisis. A process of this nature involving both apices is tuberculosis in over 99 per cent of cases.

DR. KING: This introduces a new factor, tuberculosis. I am sure Dr. Lingley agrees that we have had cases of idiopathic pulmonary fibrosis that showed lesions involving the upper lobes as well as the rest of the lungs. But I agree with him that lesions predominantly in the upper lobes, like these, are almost always tuberculous.

Do you see evidence of active tuberculosis? It is clear that the outpatient physician had this in mind, because one sputum specimen was examined for tubercle bacilli.

DR. LINGLEY: I cannot express an opinion on that point, as I dislike calling a lesion active without two or more examinations at intervals.

DR. KING: So far then the x-ray has added the fact that tuberculosis is probably the underlying cause of the pulmonary fibrosis that is present.

Now I want to ask one other question. Do you see evidence of pulmonary thrombosis or embolism, or of recent or old infarcts caused therefrom?

DR. LINGLEY: No.

DR. KING: This is as good a time as any to take up another possible factor in pulmonocardiac deaths. The reported cases of chest deformity eventually leading to death are those of extreme kyphoscoliosis. Personally I doubt that the pigeon breast was a significant factor in this case.

What about the x-ray appearance of the heart?

DR. LINGLEY: The heart does not appear enlarged in either the posteroanterior or the lateral

view. However, the very marked depression of the fourth segment and xiphoid of the sternum undoubtedly has produced rotation of the heart. Moderate enlargement could be present and yet not visible because of the degree of rotation. It is surprising that with this amount of depression of the sternum, producing marked pressure on the heart, there is no lateral or posterior displacement.

DR. KING: Because of the low diaphragm and the rotation of the heart, the picture is not inconsistent with right-sided enlargement?

DR. LINGLEY: No; it may be present, but I cannot prove it.

DR. KING: Is the pulmonary artery dilated?

DR. LINGLEY: It is prominent in the posteroanterior view, but again, rotation confuses the picture. The normal pulmonary artery would be prominent in this view if the heart were rotated.

About all the information I can give you is that there are marked emphysema and bilateral tuberculosis, and that the lower sternum and xiphoid produce marked pressure on the heart, rotating but not displacing it.

DR. KING: Finally we have the electrocardiogram. From the clinical standpoint I expect Dr. Bland to say that the electrocardiogram shows right-axis deviation and is therefore consistent with right-sided heart failure. However, Dr. White states that 50 per cent of the cases of chronic cor pulmonale have coronary disease, and I am particularly anxious to know if Dr. Bland believes that the electrocardiogram gives evidence of coronary disease or any findings that cannot be explained on the basis of chronic cor pulmonale.

DR. EDWARD F. BLAND: There is definite right-axis deviation, which is consistent with cor pulmonale. There is no evidence of coronary disease insofar as the electrocardiogram goes.

DR. KING: I am now ready to make the final bid. I shall say: pulmonary emphysema and emphysematous blebs; pulmonary fibrosis, probably on a tuberculous basis, but with no evidence of active pulmonary tuberculosis; chronic cor pulmonale, with dilatation and hypertrophy of the right ventricle; congestion of the liver, with ascites.

DR. S. P. SARRIS: Would you consider pericardial fixation in this case? Could the pain twenty-five years previously have been of pericardial origin?

DR. KING: I do not believe that we can pay much attention to that story of pain, which I interpret as having been due to pleurisy.

I do believe that constrictive pericarditis should be mentioned as a possible cause of the distended veins and liver, with ascites and edema. However,

*White, P. D. *Heart Disease*. 931 pp. New York: The Macmillan Company, 1931. P. 408.

I do not see the evidence for such a diagnosis in this case, and believe that another and more adequate diagnosis has been established.

DR. LINGLEY: In this case, could not the depression of the sternum alone produce *cor pulmonale*?

DR. BLAND: It hardly seems sufficient in this case, but a marked funnel chest can ultimately cause *cor pulmonale*.

CLINICAL DIAGNOSES

Cor pulmonale.
Pulmonary fibrosis.
Cardiac failure.

DR. KING'S DIAGNOSES

Pulmonary emphysema and emphysematous blebs.
Pulmonary fibrosis, probably on a tuberculous basis, but without active pulmonary tuberculosis.
Chronic *cor pulmonale*, with dilatation and hypertrophy of right ventricle.
Chronic congestion of the liver with ascites.

ANATOMICAL DIAGNOSES

Cor pulmonale.
Pulmonary fibrosis.
Pulmonary emphysema.
Thrombosis of left pulmonary artery.
Pulmonary tuberculosis, with cavitation.
Ulcer of cecum, tuberculous.
Pleuritis, fibrous.
Anasarca.
Meckel's diverticulum.
Pigeon breast.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: Since Dr. King suggested the analogy with contract bridge I cannot resist, despite the excellence of his discussion, pointing out that in this case he was dealt what is often called a "pianola hand." Most of the possible causes for *cor pulmonale*, phthisis, emphysema, pulmonary fibrosis, pulmonary thrombosis and thoracic deformity were simultaneously present, so he could scarcely go wrong. Which of these various factors played the predominant role is quite impossible to say, and a synergistic action seems most probable.

A note by Dr. Howard Sprague on the patient's first admission runs as follows:

Cyanosis of face and hands. Veins distended, but patient lies flat without much discomfort. Greatly diminished breath sounds, especially over the back; occasional moist rales; heart size impossible to deter-

mine clinically, but not increased according to x-ray films; sounds distant; rhythm normal; a third sound heard; neither aortic nor pulmonic second sound accentuated. Impression: I believe this to be chronic *cor pulmonale* based on pulmonary fibrosis and emphysema, with final congestive failure. I do not find enough evidence for a diagnosis of mitral stenosis. He may have an adherent pericardium, but the pleurisy occurred forty years ago so I do not believe Pick's syndrome is present.

The post-mortem examination showed a high degree of *cor pulmonale*. Both the right auricle and the right ventricle were dilated, and the latter measured 8 mm. in thickness as compared with 13 mm. for the left ventricle. The pulmonary valve ring measured 10.5 cm. compared with 8 cm. for the aortic, and the tricuspid valve was 16 cm. in circumference. The pericardial cavity was entirely free from adhesions, and there was no evidence of mitral stenosis. The lungs showed very advanced bullous emphysema with air sacs ranging up to 9 cm. in diameter in both lower lobes. In addition, both upper lobes and the right middle lobe showed scattered tuberculous cavities lined with caseous material. An additional factor, which must have played a role in the development of the *cor pulmonale*, was the presence of a large old and well-organized thrombus in the left pulmonary artery, which filled approximately two thirds of the vessel. One other evidence of active tuberculosis was an ulcer of the cecum.

Microscopic examination of the lung shows active tuberculosis in the upper lobe. Secretions from the lower lobe show extensive fibrosis and emphysema. There are many military fibrotic lesions that have a tendency to be located in regions usually occupied by lymphatics. A few of these contain giant cells, and all of them have considerable carbon pigment. They could be healed tubercles but are much more characteristic of silicotic nodules. The patient's more remote occupational history was never inquired into so we do not know whether he had exposure to silica dust. Chronic silicosis is, of course, a common cause of *cor pulmonale*. The liver showed an extreme degree of chronic passive congestion, with degeneration of the liver cells in the central two thirds of every lobule but no central fibrosis that would warrant a diagnosis of cardiac cirrhosis. The spleen was very small, weighing 70 gm. An incidental finding was a Meckel's diverticulum 100 cm. from the ileocecal valve; it contained well-differentiated gastric mucosa but no sign of peptic ulceration.

DR. SARRIS: Was any cause found for the pulmonary thrombosis?

DR. MALLORY: No underlying anatomic cause was found.

UNITED WAR FUND

THE campaign of the Greater Boston United War Fund opened officially on January 4 with a gathering of the members of the Advance Gifts Division at Symphony Hall. The final event, the period of intensive solicitation, will begin on January 21 and end on February 10. During the campaign \$7,800,000 must be contributed to cover the needs of two hundred and thirty-five hospitals and social agencies in forty-nine local communities, and of various wartime services, such as United Service Organizations, United Nations Relief Fund and War Prisoners Aid. The total is slightly greater than set and raised a year ago, a fact necessitated not by the demands of local institu-

tions, which are less, but by those incidental to the war effort.

Although many of the physicians of Greater Boston contribute generous amounts of time and energy to the local charitable organizations, their opportunities to give aid to the wartime services are practically negligible. By subscribing, they will be doing what all clear-thinking and patriotic citizens should do—support the Fund to their utmost.

ERADICATION OF MALARIA

ANOTHER article¹ has been published by the *Reader's Digest* that can only misinform and mislead the public. Unfortunately, the reader is given the erroneous conception that malaria can be eradicated by means of a five-day treatment with the synthetic drug, atabrine. False hopes will be aroused among the inhabitants of the endemic and hyperendemic malarious areas of the world, and wishful thinking among our population and particularly among our troops serving in tropical and subtropical areas will tend to minimize the seriousness of the malaria problem and of the loss of the main source of quinine in the Netherlands East Indies.

Atabrine is the best substitute for quinine that has been developed and utilized for the treatment of malaria. The drug, when properly administered by a physician or by trained personnel under the direction of a physician, cures a higher percentage of cases and lessens the relapse rate to a greater degree than does quinine. The drug can be used prophylactically to prevent clinical malaria but, like quinine, does not prevent infection.

Atabrine produces toxic symptoms in a certain percentage of persons. The drug is also accumulative, being eliminated very slowly from the body. Furthermore, atabrine has no effect on the gametocytes or so-called "crescents" of malignant tertian malaria (caused by *Plasmodium falciparum*) and hence transmission of this infection can take place even while the drug is being administered; in

such cases, a course of plasmochin, the specific for the gametocytes of *P. falciparum*, must be given to sterilize the peripheral blood. And, finally, it is well known among malarialogists that no drug or combination of drugs will produce a cure in all infected patients and thus completely destroy the seedbed of parasites in an urban or rural population where malaria is an acute problem.

The results of two extensive experiments to control malaria are cited to support the above statements. Clark, Komp and Jobbins² attempted to control malaria in a number of endemic areas in Panama over a period of ten years by making monthly parasite surveys and by treating the positive cases with two combinations of drugs—atabrine and plasmochin simplex and quinine and plasmochin simplex. These careful and experienced workers succeeded in greatly reducing the cases of severe clinical malaria but failed to eradicate malaria and to reduce transmission. They also demonstrated that drug-control methods could not prevent an epidemic if great numbers of anopheline mosquitoes were present. Cuica and his collaborators,³ working in Roumania, were also able to reduce clinical cases, relapses and malarial morbidity by the use of atabrine and plasmochin prophylactically and therapeutically. In spite of giving systematic treatment to all cases of malaria, the parasite-carrier rate—the seedbed of the infection—remained about the same. Suspension of treatment after three years was followed by an increase of the clinical cases to the level that had existed before the experiment was started. The latter group also showed that the length of treatment with atabrine should be seven days, and that the drug causes toxic symptoms in a certain percentage of cases, particularly in children under one year of age. They also emphasized that the administration of synthetic malarial drugs should be under medical supervision.

The final solution of the diversity of problems in the control and eradication of malaria does not depend alone on the per capita cost of atabrine or of any other malarial drug. The claims

made for the use of a drug in one area do not necessarily apply to another where the infection may be more widespread and more serious clinically. The cost of mosquito control, where such a program is feasible, is often great, requiring the maintenance of trained field workers (entomologists and engineers) and laboratory and medical staffs. When this item is considered, the cost of malaria control increases greatly and many localities or governments cannot support and maintain the program.

It is quite easy to say, "Thanks to atabrine, the fiendish disabler can now be wiped out, if we will have the will to try." It should be pointed out, however, that the work of malarialogists, entomologists, engineers, chemists and pharmacologists has advanced knowledge greatly during the past decade. Their evidence and advice is informed and reliable and not prone to mislead the public.⁴ These men, many of whom are risking their lives in the study of malaria, know that no ideal drug for the treatment of malaria has been discovered and that no known methods for the eradication of malaria have been successful. And, once again,⁵ it must be emphasized that the editors of periodicals in which articles conveying such impressions are published would do well to consult experts in the fields concerned before releasing them for lay consumption. Articles of this sort do not help, they only hinder, the battle against disease and the winning of the war.

MEDICAL EPONYM

SNELLEN TEST TYPES

These types were introduced by Dr. Herman Snellen (1834-1908) in a pamphlet published at Utrecht in 1862. Six versions, Latin, English, French, Italian, German and Dutch, appeared simultaneously under the title, *Test Types for the*

Determination of Vision. The following is a translation from the German edition:

In order to determine the visual acuity, we measure the smallest subtending angle at which objects of known size and shape can be distinguished. . . . Square letters, the lines of which are a fifth of the height in thickness, are usually distinctly perceptible to the normal eye when subtending an angle of 5 minutes. The number over the letters expresses in Paris feet the distance at which the letters are seen when subtending an angle of 5 minutes.

The visual acuity (S) [later v] is expressed by the relation of the distance (d) at which the latter is recognized to the distance (D) at which it subtends an angle of 5 minutes.

$$S = \frac{d}{D}$$

If we find d equal to D and consequently No. 20 is seen at a distance of 20 feet, then $S = \frac{20}{20} = 1$; that

is, the visual acuity is normal. If, on the other hand, d is less than D , so that No. 20 is seen only at 10 feet, No. 10 only at 2 feet and No. 6 only at 1 foot, then the visual acuity in these cases is respectively,

$$S = \frac{10}{20} = \frac{1}{2}$$

$$S = \frac{2}{10} = \frac{1}{5}$$

$$S = \frac{1}{6}$$

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON MATERNAL MORTALITY

ANALYSIS OF CAUSES OF MATERNAL DEATH IN MASSACHUSETTS DURING 1941

ANESTHESIA

Ten maternal deaths due to anesthesia occurred in Massachusetts during 1941. There were 3 autopsies in this series of cases.

The first case was that of a primipara who after a test of labor was delivered by Waters's cesarean section. While the patient was going under anesthesia, gastric contents were aspirated; blood-tinged sputum appeared one hour after delivery, and x-ray films showed consolidation in the right upper lobe. She was put in an oxygen tent after delivery, bronchoscopy was performed and sulfathiazole treatment was instituted, but death occurred three days after delivery. Autopsy revealed massive pulmonary edema and bronchopneumonia. The patient was given the full advantage of present-day knowledge, and in retrospect the vomiting during oper-

ation can only be looked on as a most unfortunate incident.

The second patient, a multipara who had one living child, entered the hospital in active labor with the head on the perineum. During the administration of nitrous oxide and oxygen anesthesia, which was given by an obstetric supervisor, the patient became black and vomited; the mask was removed, and she regained consciousness; when the anesthesia was again started she became cyanotic and died. Twins were delivered, and both babies lived. It would have been, of course, far better if this patient had been allowed to deliver herself without anesthesia; the vomiting during anesthesia, however, would probably not have occurred if an inhalation anesthetic had not been used. This case raises the interesting question of whether spinal anesthesia should not be more widely used for delivery; in the hands of one experienced in its use it does not carry the danger of nausea and vomiting.

The third case was that of a primipara who had been delivered by low forceps of a living child; during repair of the episiotomy wound, respirations ceased and the patient did not breathe again. According to the medical examiner's report, based on an autopsy limited to the head, this death was due to nitrous oxide asphyxiation. Surely this death was regrettable if not reprehensible.

The fourth case was that of a primipara who, because of cephalopelvic disproportion, was being prepared for cesarean section, which was to be performed under spinal anesthesia. Twenty milligrams of Pontocaine were injected into the spinal canal, immediately following which the respiratory and cardiac centers became paralyzed, and in spite of stimulants, death occurred two hours later. This death was undoubtedly due to spinal anesthesia. This anesthetic was probably not given by an experienced anesthetist, for 20 mg. of Pontocaine is an astoundingly large dose.

The fifth patient, a primipara who was delivered by low forceps, vomited food as she was coming out of anesthesia. Bronchoscopy was performed and pieces of food were removed; but massive collapse of the lung developed, and the patient died four hours post partum. Nitrous oxide, oxygen and ether was used in this case. There is no evidence in the record that any of the barbiturates were used. This fatality emphasizes the danger of inhalation anesthesia when the stomach is filled with food.

The sixth patient, a woman in her third pregnancy and at term, had a separated placenta, which was treated conservatively by rupture of the membranes and packing the cervix. She was delivered by low forceps after full dilatation. She had vom-

ited while going under ether, and bronchoscopy showed evidence of aspiration. In spite of suction, the patient gradually went downhill, and died four hours after delivery. This case merely emphasizes the potential seriousness of vomiting.

The seventh patient was a primipara who was given ether at the very end of labor and for episiotomy repair. During the administration of the anesthetic vomiting occurred; acute edema of the lungs resulted, and death followed in eight hours. Autopsy revealed *bilateral acute pneumonitis with bilateral hydrothorax*. Since this patient was convalescing from an upper respiratory infection when labor started, it is barely possible that the infection had some bearing on the fatality, although it seems more likely that the anesthesia was the determining factor in view of the few hours that elapsed between delivery and death.

The eighth patient, who had two living children, started in labor at home, and the cord prolapsed. She was sent to the hospital in Trendelenburg position. Under nitrous oxide and ether anesthesia version was accomplished and a stillborn child delivered. Cyanosis appeared before delivery of the placenta, and death followed immediately. This must be considered an anesthetic death. Whether or not the long period the patient was in the Trendelenburg position had anything to do with the pulmonary congestion is an academic question.

The ninth patient was a primipara who, while on the operating table under nitrous oxide, oxygen and ether anesthesia, aspirated vomitus into the trachea and lost consciousness, which she did not regain, death occurring ten hours after delivery. Although this patient had had 6 gr. of Nembutal several hours before delivery, it is not quite fair to attribute the fatality in any way to the medication. This case emphasizes the importance of anesthesia administration by trained anesthetists at the time of delivery.

The history of the tenth and final case is inadequate. A patient at term was given spinal anesthesia before cesarean section, and although the death certificate attributes this death to acute cardiac dilatation it was more probably due to the spinal anesthesia.

All these deaths from anesthesia seem to have been preventable as well as unfortunate.

DEATHS

BRACKETT — ELLIOTT G. BRACKETT, M.D., of Boston, died December 28. He was in his eighty-third year.

Born in Newton, he attended Newton High School and received his degree from Harvard Medical School in 1886. In 1917 he was appointed as director of orthopedic surgery for the Army. He was a former director of the Orthopedic General Hospital and was the first president of the

Boston School for Occupational Therapy. He was one of the founders of the Industrial School for Crippled and Deformed Children and at the time of his death was the editor of the *Journal of Bone and Joint Surgery*.

Dr. Brackett was a fellow of the Massachusetts Medical Society and the American Medical Association. He was also a member of the American Academy of Orthopaedic Surgeons and the American College of Surgeons.

His widow survives him.

LUCY — JOHN J. LUCY, M.D., of Boston, died December 28. He was in his forty-eighth year.

Born in Boston, he attended Boston College and received his degree from Harvard Medical School in 1920. He was assistant chief surgeon at the Boston City Hospital and was a staff member of the Cambridge Hospital. Dr. Lucy was a member of the Massachusetts Medical Society and the American Medical Association. He was also a fellow of the American College of Surgeons.

His widow, his mother and seven children survive him.

MACLEOD — HARRY F. MACLEOD, M.D., of Boston, died December 21. He was in his seventy-second year.

Dr. MacLeod received his degree from the University of Pennsylvania School of Medicine in 1894. He was a former member of the Massachusetts Medical Society.

A son survives him.

MALONE — CHARLES MALONE, M.D., of Jamaica Plain, died October 10. He was in his sixty-eighth year.

Dr. Malone received his degree from Tufts College Medical School in 1902 and since that time had practiced in Jamaica Plain. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

Two sons and a daughter survive him.

MANEY — JOHN J. MANEY, M.D., of Lawrence, died December 11. He was in his sixty-eighth year.

Dr. Maney graduated from Tufts College, and received his degree from Baltimore Medical College in 1900. He was a former member of the Massachusetts Medical Society.

A son, four brothers and three sisters survive him.

MISCELLANY

DOCTORS AT WAR

On December 26, the American Medical Association and the National Broadcasting Company, in official co-operation with the Medical Department, United States Army, and the Bureau of Medicine and Surgery, United States Navy, began the third series of the coast-to-coast radio broadcast, "Doctors at War," the current series being entitled "Doctors at War." These broadcasts will be continued for twenty-six consecutive weeks and are scheduled at 8:00 p.m. (EWT) on Saturday. They consist of short dramatizations that give a vivid picture of the work of physicians in the Army, in the Navy, in industry and at home.

CORRESPONDENCE

MASSACHUSETTS TUBERCULOSIS LEAGUE

To the Editor: In behalf of the Massachusetts Tuberculosis League I wish to express my appreciation for the

splendid editorial on the Christmas Seal Campaign in the December 10 issue of the *Journal*.

You may be interested to know, in connection with your statement that the seals, among other things, are partly "to provide x-ray equipment and other diagnostic facilities for kindred purposes," that the directors of the League voted to underwrite the purchase of a portable 4-by-5-inch photoröntgenographic unit for use in defense and other industrial plants and in high schools. The equipment mounted on a special motor truck will cost about \$14,000. Many of the affiliated branches of the League have already allocated 3 per cent of their 1943 Seal Campaign receipts toward the cost of this apparatus. It is to be hoped that all will contribute a like amount so that no more than \$5000 will have to be taken from the reserve fund.

Arrangements have been made to lend this unit to the Division of Tuberculosis of the Massachusetts Department of Public Health: they will operate it with their present personnel and will be responsible for its maintenance. This new type of film, because of its smaller size, costs only one tenth as much as the film in general use. It is therefore possible to x-ray many more persons without increasing the outlay for this best of all case-finding procedures. Under the plan men and women will receive the benefit of an examination that is now the privilege of those entering military service. Furthermore, to have the official and voluntary health agencies working in close harmony and pooling their resources to make more effective the attack on tuberculosis is a noteworthy achievement in co-operation.

HENRY D. CHADWICK, M.D., *President*
Massachusetts Tuberculosis League, Inc.

BOOK REVIEWS

Personality and Mental Illness: An essay in psychiatric diagnosis. By John Bowlby, M.D. 8°, cloth, 280 pp. New York: Emerson Books, Incorporated, 1942. \$2.75.

This book is well written, and the writer makes some perfectly good points. He believes that it is absurd to avoid the fact that the personality before the onset of overt mental disease is of great importance. He is also quite properly impressed with the relative futility of dividing off the psychoneuroses from the psychoses.

The attempt to rearrange classification and to catalogue specific and nonspecific traits that can be used in appraising a mentally ill patient is interesting. The difficulty, which is quite obvious to the author as well as to the reviewer, is that the theoretical discussion is not convincing without a vast amount of evidence, which certainly is not presented in this volume and which can hardly be supplied until large numbers of cases are watched over many years.

Skin Grafting from a Personal and Experimental Viewpoint. By Earl C. Padgett, M.D. 4°, cloth, 149 pp., with 65 illustrations and 3 tables. Springfield, Illinois: Charles C Thomas, 1942. \$4.50.

This book embodies the material of Dr. Padgett's clinical as well as experimental work. After a brief historical outline of the gradual progress of the methods of skin grafting during the span of a century and a half, the author discusses the interesting problem of homotransplantation and heterotransplantation methods. From his clinical as well as experimental evidence he concludes that

autotransplantation of skin usually succeeds; that syngenesiotransplantation of skin is theoretically improbable except in identical twins, in whom it is theoretically probable and has been accomplished clinically; and that, for all practical purposes, homotransplantation of skin may be relegated to the realms of medical mythology.

The author next considers methods of cutting skin grafts, and emphasizes the superiority of the dermatome, especially when it is necessary to remove a large piece of skin of uniform thickness. There is no doubt that this instrument, introduced to the profession by the author, has filled a great need and has contributed a good deal to the progress of skin grafting. However, in the opinion of the reviewer, the time-honored method of using a razor-edge knife still has its place, especially when a very thin skin graft or grafts of small size are needed.

Dr. Padgett discusses the relative merits of pedicle grafts and their indication as compared with skin grafts, and properly emphasizes the importance of well-conceived and well-planned pedicle grafts.

The book is printed on coated stock, with many photographs and illustrations of different cases. There are several statistical tables.

Although the literature of skin grafting is abundant in medical periodicals and books, this small volume will undoubtedly occupy a place in the library of those who are particularly interested in traumatic surgery.

Pediatric Gynecology. By Goodrich C. Schauffler, M.D. 8°, cloth, 384 pp., with 66 illustrations. Chicago: The Year Book Publishers, Incorporated, 1942. \$5.00.

The dust wrapper of this book carries the words "a pioneer book by a pioneer worker." They are true words. There exists no other book, the reviewer is quite sure, that covers the ground of this one. Most pediatricians surely and gynecologists probably know very little indeed about the disorders of the immature female genitalia. With the power to make correct diagnoses they would probably have difficulty in deciding how to treat even halfway adequately.

This treatise supplies a good many of the inadequacies in this knowledge. The author furnishes an abundance of concrete facts, and his conclusions concerning treatment and method of approach — for in such a field, tact and delicacy as well as judgment are of the highest importance — have the earmarks of practicality and good common sense. His technics, it is true, come far more naturally to the gynecologist than to the pediatrician. To the latter, indeed, the greatest value of the book is in teaching him when to look to the former for assistance, what that assistance should be and what may be expected from it. The book steps over even into urologic, proctoscopic and medicolegal fields.

It is an original book and an important book, which is highly recommended.

From Infancy through Childhood. By Louis W. Sauer, M.D., Ph.D. 12°, cloth, 200 pp., with 13 illustrations and 5 charts. New York: Harper and Brothers, 1942. \$2.00.

This is another manual for home consumption on the care and management of infants and children. The author is a pediatrician of experience and a safe and sane guide in such matters; moreover, his advice is brief and clear. The wonder arises, however, why author or publisher should have deemed worthwhile this excursion into a field already so well covered: there are books and books on the subject, all of which, in essence, repeat the same things. And this is just one more.

NUMBER 2

THE HISTORY OF THE DISCOVERY AND ISOLATION OF THE MALE HORMONE

GERRARD J. NEWERLA, MD

ALBANY, NEW YORK

THE first knowledge of testicular function was acquired empirically by the ancients when domestic animals were castrated for various reasons. However, the specific effects in men were also familiar to those early civilizations where eunuchs were a part of the social order. Furthermore, the *Ayurveda*, by Susruta of India,¹ written about 1400 B.C., recommended the administration of testicular tissues for the cure of impotence. From these times until within the past twenty years, with the exception of very few animal experiments in the middle of the eighteenth and nineteenth centuries, the knowledge of the secondary functions of the gonads did not advance much beyond the facts known in the Middle Ages.

With some degree of overlapping, the investigation of the endocrine functions of the testes may be grouped with a certain fitness into the following periods: speculative and observational; experimental; and analytic and synthetic.

SPECULATIVE AND OBSERVATIONAL PERIOD

The customs of primitive people and society until rather recent times dictated forms of organo-therapy and the use of organs as medicine, such as the eating of hearts from animals, or even from man, to encourage bravery, or the use of brain as food to counteract idiocy. Perhaps it was for such reasons that the ancients and the people of the Dark Ages indulged in organo-therapy, especially of such substances as bile, blood, bones, dung, brains, feathers, horns, intestine, placenta, reproductive organs and teeth. Often the difficulty of obtaining a part was its most attractive attribute. Nothing was too disreputable for use. *Dieck Apotheken* specialized in secretions and excretions,² but other books, especially Heberden's³ *Antitheriaca* (1745), discredited these disgusting preparations. It is interesting to note that today many of the sex hormones, including that of

the male, are obtained from human waste products.

The type of therapy employed by medieval physicians is an indication of their conception of the nature and cause of disease. At a time when disease was treated according to a jumble of mysticism, philosophy and dogma, critically appraised concepts of the action of even the exocrine glands could not be formulated. There are some physiologic statements which in the light of modern knowledge show glimpses of suspected fact. A vague foreshadowing of the endocrine function of the testis can be found in the works of Aretaeus,² the Cappadocian (ca 150 A.D.), in the chapter on gonorrhea: "For it is the semen, when possessed of vitality, which makes us to be men, hot, well braced in limbs, well voiced, spirited, strong to think and act. For when the semen is not possessed of its vitality, persons become shrivelled, have a sharp tone of voice, lose their hair and their beard, and become effeminate, as the characteristics of eunuchs prove." Rolleston⁴ mentioned that Johannes Mesue, the Elder (777-837), prescribed testicular extracts as an aphrodisiac and against pulmonary tuberculosis. Some real understanding of the problem was first voiced in 1775 by Théophile de Bordeu, a graduate from Montpellier and a physician at the court of Louis XV. He was the founder of the theory of vitilism, and strove to show that the humoral pathology of Hippocrates was due to bodily secretions. For many organs and their secretions he enumerated specific diseases. In this manner he arrived at the concept that each organ of the body produces a substance which enters the blood stream and that the sum total of these forces regulates bodily functions. He even cited the well recognized underdevelopment of secondary sexual characteristics in eunuchs, capons and spayed female animals in connection with the absence from the blood of specific secretions of the gonads. In his book, *The Medical Analysis of Blood*, he⁵ came to the con-

clusion that "each [of these organs] is a store room and laboratory for a particular humor [substance] which is given off into the blood after it has been prepared in its bosom [that is, the organ], and has thus conferred upon it [the humor] a radical [specific] character."

These views are very similar to those expressed by Brown-Séquard,⁶ and are practically identical with the modern definition of endocrine function. Speaking of testicular secretions, de Bordeu⁷ stated: "I accept as fully demonstrated medically the view of such continuous emanations from each organ into the blood. And if we take into consideration the facts discovered by anatomists with regard to the existence of the lymphatics, I would say that the gelatinous liquor [that is, the semen of the testis] is sent into every organ of the body by certain vessels, and confers upon the chyle in the thoracic duct the properties and peculiarities of the 'ingredients' of which they are composed." He believed that the gross structure of the cellular tissue was the chief site of exchange of these secretions, since the true dimensions of the lymphatic network were still incompletely known. No one prior to Berthold,⁸ or even Brown-Séquard, visualized as closely as did de Bordeu the true mode of action of the endocrine glands. Neuburger⁹ in 1911 emphasized the approximation of de Bordeu's speculation to the mechanism of internal secretions by ductless glands. Yet others consider the uncritical writings of de Bordeu as an attempt to classify cachexias resulting from various secretions, excretions and organs in a none too discerning fashion. Garrison,¹⁰ in the "History of Endocrinology," writes: "The book is a typical example of the purely theoretical reasoning so common in the medical literature of the eighteenth century, in which an intolerable deal of verbiage is spread over the smallest substructure of fact." He regarded the sexual secretions as giving "a male—or female—tonality" to the organism, "setting the seal upon the animalism of the individual." Observations regarding castration, known to animal-breeders since much earlier times, were confused by him with hearsay reports and anecdotes, and did not induce him to test his ideas experimentally. The historian must remain on guard so as not to read modern concepts into fanciful hypotheses.

During this period of speculation, some progress was made in the study of the anatomy and physiology of the ductless glands. Aristotle, in his *Historia Animalium*, written prior to 300 B.C., described the testes and ovaries in many species of animals and showed a clear conception of the effect of castration. In book nine of the fourth volume he¹¹ wrote: "If the bird be full-grown [when castrated] his crest grows fallow, he ceases

to crow, and foregoes sexual passion; but if you cauterize [that is, castrate with hot irons] the bird when young, none of these male attributes or propensities will come to him as he grows up. The case is the same with men; if you mutilate them in boyhood, the later-growing hair never comes, and the voice never changes but remains high-pitched; if they be mutilated in early manhood, the late growths of hair quit them except the growth in the groin, and that diminishes. . . ."

While the knowledge of secretions of the testes, other than the semen, gradually evolved, the study of glands in general, and of the ductless glands in particular, formulated many fundamental principles that applied to all internal secretions. Galen knew of the existence of the pituitary gland, although Vesalius¹² described it first in 1543 and named it after the Latin word *pituita*, meaning "mucus" or "phlegm,"—which, as both believed, was secreted by it. Schneider¹³ in 1655 and Lower¹⁴ in 1670 proved that such mucus did not pass from the brain to the nose, and suggested an internal secretion of this gland. Willis¹⁵ in 1664, according to Rolleston,¹⁶ believed that "the blood poured out something—through the spermatic arteries to the genitalia—and that it received in turn certain ferments from these parts,—that is, certain particles imbued with a seminal tincture and carried back to the blood,—which makes it vigorous and instills into it a new and lively virtue."

Gley¹⁷ claimed that Legallois¹⁸ in 1801 had come more closely to the concept of internal secretion than had de Bordeu. Legallois found that although arterial blood was of the same composition throughout the body, venous blood varied considerably, depending on the site from which it was obtained. This difference he attributed to the fact that the organs removed something from the blood, which then passed into the veins. This claim is scarcely as impressive as that of Willis and of Lower.

Thus, in less than half a century, ductless glands were recognized as closely allied to the vascular system and capable of secreting a substance into the blood stream. The close association with the blood vessels was pointed out by Broussais¹⁹ in 1817 for the spleen and the adrenal, thyroid and thymus glands, and by Béclard²⁰ in 1823 for the pituitary and pineal glands. Johannes Mueller²¹ in 1834 and Henle²² in 1841 differentiated between glands with and without ducts, and believed that the ductless glands changed the composition of the blood.

One may say that ancient and medieval scientists formulated certain philosophical theories on glandular secretions. These hypotheses, when read

from a modern point of view, seem to indicate in many instances a fair comprehension of the presence and function of the endocrine secretions, especially those of the testis. Such an assumption, however, is pure inference, and these concepts may not have been so clearly formulated in the minds of the philosophers, who based their conclusions on a few casual observations.

EXPERIMENTAL PERIOD

Many centuries had passed since Aristotle ascribed pubertal changes to the function of the gonads, as such manifestations were absent in castrates. In the era of enlightenment, objective study was combined with sound reasoning by many anatomists and scientists, until John Hunter and Berthold approached the problem experimentally. John Hunter²³ in 1762 attempted to ascertain whether the genital organs of one sex could be grafted to and grow in the body of the opposite sex. He transplanted the testicles of a cock into the abdomen of a hen, and in several cases found that some grafts had taken root there, but "did not come to perfection." For this reason he considered the experiments as incomplete and of no value. However, he failed to mention any "masculinization" effects observed with the few successful transplants.

In 1848, Berthold,⁸ then professor of physiology in Göttingen, removed the testes of four roosters and replaced one testis in an unusual abdominal position in each of two capons. He killed these two capons six months later, and found that because of the testicular grafts "these animals remained male in regard to voice, reproduction instinct, fighting spirit, and growth of comb and wattle. . . . The consensus [that is, the interrelation of function among different parts of the body] is maintained by the productive influence of the testicle; that is to say, by its effect upon the blood, and through the blood, upon the organism."

Berthold's clear and important demonstration of endocrine secretion was published in a five-page paper which remains the only noteworthy epitaph of an author who wrote voluminously on other subjects. Rudolf Wagner,²⁴ the physiologist, could not confirm Berthold's findings in 1850, and the influence of the discovery was almost forgotten until Biedl,²⁵ in his monograph, *The Internal Secretions*, resurrected the work and bestowed on Berthold "the honor of having first proved the existence of an 'internal secretion' and of having recognized its significance."

By 1850 the long-recognized influence of the testis had been demonstrated to be caused by blood-borne secretions of these ductless glands. These facts were disregarded, however, and it was

only after impressive experiments in the field of metabolism that inferences were drawn regarding endocrine organs. Great progress followed the work of Claude Bernard,²⁶ who in 1843 proved that cane sugar is changed to dextrose by gastric juice. These results became widely known, and as Garrison²⁷ remarks regarding internal secretions, "It was the fact that glycogen [Bernard's *sécrétion interne* of the liver] could be seen, touched, tasted and experimented upon, as such, that established the theory of internal secretions as a working principle in physiology."

At the time of Bernard's studies, Thomas Addison²⁸ extended to the adrenal gland the principle of glandular hypofunction, which had been recognized for centuries with regard to the testes, but had not been known to apply to the other glands. His classic description of the disease of the adrenal glands that now bears his name was verified within a year by Brown-Séquard,²⁹ who extirpated the adrenal glands and found that the animals showed the symptoms described by Addison.

The latter part of the nineteenth and the early part of the twentieth century was a period in which general principles were outlined. Bernard had formulated the concept, *la fixité du milieu intérieur*, or the constancy of the internal environment, by which he meant that higher animals maintained a constancy of temperature and bodily fluids. It became known that the endocrine system, in conjunction with the nervous system, especially with the autonomic portion, aided greatly in maintaining the remarkably even tenure of involuntary bodily activities.

A slight digression is in order for the purpose of tracing the development of the fundamental nomenclature of endocrine secretions. According to Rolleston,³⁰ the term "internal secretion" was first used by Claude Bernard in a lecture at the Collège de France on January 9, 1855. Speaking of his work in glycogenesis, Bernard said that the liver had an "external secretion" of bile and an "internal secretion" of sugar, which passes directly into the general circulation.

Bayliss and Starling,³¹ in 1903, believed that the term "internal secretion" inadequately expressed the widespread action on the body as a whole of chemical entities produced in certain organs, and transported elsewhere by the blood and the lymphatics. Starling,³² in the first Croonian Lecture before the Royal College of Physicians, on June 20, 1905, spoke of "the chemical messengers or 'hormones' [I excite or arouse]." According to Rolleston³³ this word was suggested by W. B. Hardy after consultation with W. T. Vesey from Caius College, Cambridge.

In the early years the selection of the term "hormone" was frequently criticized on the ground that it applied by definition only to substances that have a stimulating action, and failed to include those that had an inhibiting or depressing effect. Yet Jayle³¹ stated that this word or its derivatives had already been used by Hippocrates. Likewise John Smith,³² a physician from Brasenose College, Oxford, used it in his *Gaerokomia Basilikae*, when he spoke of the "hormetick power and concentration" of the muscles. Schäfer,³³ in his book, *Endocrine Organs*, suggested the term "hermone" (from Hermes, "messenger"), which would exclude any ambiguity and could be applied to both stimulating and depressing agents. In 1913, he³⁷ had already advanced the term "chalone" ("I loosen") for the inhibitory hormones and the word "autocoid" ("self-remedy") as a generic name for all internal secretions, and reserved the noun "hormone" exclusively for stimulating agents. The use of these terms, however, did not become popular, and is at present largely discontinued.

Pende,³⁸ an Italian, had introduced the term "endocrinology" ("I separate within") in 1909, while Gley,³⁹ a Frenchman, suggested the term "harmazone" ("I regulate") for the morphogenetic and growth-controlling secretions of the gonads and thyroid and pituitary glands at the International Congress of Medicine in London in 1913. The word "parahormone" was chosen to denote metabolic products, such as carbon dioxide, which act like hormones at a distant site.

Ironically, after a period of brilliant experimentation, clinical endocrinology was introduced by the uncontrolled study and blatant claims for rejuvenation in 1889 by Brown-Séquard,⁶ who at the age of seventy-two injected himself with aqueous extracts of the testes. He claimed as results an improvement in general health, muscular strength and appetite, and regulation of the intestinal tract and mental faculties. He⁴⁰ even suggested orchitic extracts as a panacea and advised their use, for example, in *tabes dorsalis*.

Preparation and critical investigation of extracts were logical steps in this practical period of endocrinology, and Brown-Séquard's statement of the principles involved was essentially correct. Garrison⁴¹ summarizes Brown-Séquard's ideas as follows:

All the tissues, in our view, are modifiers of the blood by means of an internal secretion taken from them by the venous blood. From this we are forced to the conclusion that, if subcutaneous injections of the liquids drawn from these tissues are ineffectual, then we should inject some of the venous blood supplying these parts. . . . We admit that each tissue, and more generally, each cell of the organism, secretes on its own

account certain products or special ferments, which, through this medium, influence all other cells of the body, a definite solidarity thus being established among all the cells through a mechanism other than the nervous system. . . . All the tissues [glands or other organs] have thus a special internal secretion and so give the blood something more than waste products of metabolism. The internal secretions, whether by direct favorable influence, or whether through the hindrances of deleterious processes, seem to be of great utility in maintaining the organism in its normal state.

This is the theory of de Bordeu, restated at a stage in the development of science when accrued knowledge permitted more precise formulation. The preceding quotation shows beyond doubt that Brown-Séquard clearly believed that the endocrine glands liberate active substances into the blood stream. This passage is markedly different from his views in 1855, when he²⁹ stated that extirpation of the adrenal glands permitted accumulation of pigments in the blood, these pigments becoming poisonous in the absence of detoxification by the glands.

The unfortunate parts of Brown-Séquard's work were the uncritical manner of investigation and the extravagant claims of rejuvenation. With the possible exception of the search of Ponce de Leon, the ageless quest for perpetual youth was never brought so closely and so attractively to the attention of the world. The limitations in the technics of grafting of the testes and in administration of testicular extracts were overlooked. Much of his so-called therapy was useless and unapproved by competent contemporaries or successors of Brown-Séquard. The susceptibility of many minds in matters pertaining to sex and the false hopes raised by extravagant claims led inevitably in a pendulum fashion to a viewpoint strongly antagonistic to the acceptance of the efficacy of any testicular substances, an opinion well warranted until the last few years. Early experiences with inactive ovarian mushes and dried matter increased the skepticism concerning the usefulness of gonadal preparations (Novak⁴²). The inevitable result was that strong prejudice for and against a mode of therapy has been built not on controlled observation and experimentation, but on wishful conclusions, inactive preparations and useless grafting operations. When active chemical substances of known, measurable and stable potency were prepared in 1936, there was already a great superstructure of largely discrediting data purportedly related to the method of substitution therapy, but in actuality proving not that the principle is incorrect, but that the technics previously utilized in substitution therapy were inadequate. This distinction must be made between the use in human beings of testicular grafts or extracts in contrast to

the present-day employment of crystalline compounds.

The unsavory aroma of attempts at rejuvenation did not prevent rapid advances in clinical endocrinology. It is interesting to speculate on the course of events had Brown-Séquard tried his theory of *autotherapy in hypothyroidism* instead of in attempted rejuvenation. Yet his work in attracting world-wide attention encouraged trial of substitution therapy in states of deficiency resulting from the poor functioning of other glands.

Overactivity of the endocrine glands, by the nature of the phenomena involved, was a matter appreciated more slowly than were deficiencies in glandular activities. The testis, the gland in which hypoactivity and endocrine secretion were first demonstrated, is not known to produce any striking sequelae of hyperactivity. Precocious sexual development is occasionally seen with interstitial tumors of children, but the condition of masculinity is not known to exceed the stage seen in normal men.

Although principles were formulated and rapid progress made in investigation of other endocrine glands, the study of testicular function advanced slowly, and on many fronts there was only a marking of time. Interrelations with other glands, particularly with the pituitary, were clearly demonstrated by studies of these glands, notably in the work of Rathke,⁴³ Frölich,⁴⁴ Cushing,⁴⁵ Evans⁴⁶ and Smith.⁴⁷

In 1908-1910, some of the details of the castrate condition in men were supplied by Tandler and Grosz⁴⁸ in a series of studies of the Skoptsy, a religious sect whose members inflicted self-mutilation according to the following advocacy in the Bible:

For there are some eunuchs, which were so born from their mother's womb: and there are some eunuchs, which were made eunuchs of men: and there be eunuchs, which have made themselves eunuchs for the kingdom of heaven's sake. He that is able to receive it, let him receive it. (Matthew xix:12.)

Additional and significant data concerning the action of male hormone substances were gleaned by animal experimentation with grafting and other manipulation of the testes (Lipschütz⁴⁹), but unhappily some studies bore the connotation of rejuvenation. A history of research of male-hormone substances would be incomplete without some mention of attempts at rejuvenation.

A chief drawback to the accomplishment of rejuvenation lies in the fact that aging affects the structure and function of cells in a manner not reversible by sex hormones. Not all cells can be expected to be restored to a status compatible with an earlier age. The use of the term "rejuvenation"

(Steinach⁵⁰) deserves severe indictment, even if applied solely to the genital organs, for the changes induced by androgenic stimulation are scarcely a "re-establishment of youthfulness." It is of fundamental importance to realize that aging occurs in various degrees in different cells, and only wishful thinking can glibly circumvent the obstacles opposing any rejuvenation merely by secretions of the testicle, even if the secretions resemble those existent when the individual was younger. It is not inappropriate to recall that in the immature boy, youth prevails without the prodding of large amounts of testicular secretions.

To those with scientific inquiry were added searchers, not of facts, but for means whereby the testis would become the fountain of youth. Charlatans reaped a financial windfall. The chief methods employed to obtain testicular secretions were implantations of a testis from another man or beast, the injection of extracts from animal testes and the stimulation to secretion of the testes already existing.

Transplantations of the testis involve a number of problems, especially satisfactory vascularization and compatibility with the environment provided by the host. Despite any excellency of operative methods, it is held in some quarters to be almost axiomatic that grafting in mammals should be to a host of the same species. Testes from goats, monkeys or other animals have not proved to have satisfactory survival and function after transplantation to man. Persistence of a mass of tissue at the site of implantation is in itself not assurance that the graft has "taken," for microscopic examination may reveal only fibrous tissue remaining. Even within the same species successful grafting is enhanced by inbreeding. Although many transplants of testes have been made from one man to another, the results have been poor, a fact not astounding in view of the difficulties of obtaining specimens in good condition, a sufficiently close relation between donor and host and a suitable endocrine status in the host. Some of the men receiving grafts have been eunuchoids in whom gonadotropins may have failed to stimulate the individual's own testes and in whom the pituitary rather than the testes have been primarily responsible for the eunuchoidism. From the standpoint of reproductive purposes, it should be noted that even if interstitial elements in the graft were to persist, the seminal epithelium would be less likely to grow satisfactorily.

Attempts to stimulate the testes of an individual can be accomplished in certain cases by the administration of gonadotropic substance. Claims have also been advanced, but without general acceptance, that testicular secretions can be augmented

by ligation or resection of the vas deferens. The theoretical basis of such operations is that the interstitial tissue is the source of androgens; that blocking of the seminal duct near the testis causes destruction of the seminiferous epithelium, presumably because of pressure; and that when the seminal epithelium is destroyed there is an increase in interstitial cells, and therefore more hormone is produced.

The period of experimentation occupied about a century and a half. Work, at first sporadic and haphazard, progressed slowly and was often misinterpreted. Berthold, about one hundred years ago, conducted experiments under the strictest control, the significance of which was fundamental and is still unimpeachable. However, the blatant claims of Brown-Séquard discouraged further advances, even though the extracts produced by him may be considered as the first attempts to isolate the male hormones. Subsequent workers advanced the knowledge of endocrinology as a whole and devised a fundamental terminology. However, the unwarranted claims of rejuvenation propounded by Steinach and by Voronoff as results of testicular grafts had the same effect as the claims of Brown-Séquard had on the studies of Berthold.

ANALYTIC AND SYNTHETIC PERIOD

Progress in the preparation of testicular-hormone extracts was slow. The lack of suitable methods for assay and the absence of adequate resources for male-hormone substances became evident, especially when compared with the high titers of female hormone found in the urine of pregnant women and domestic animals. The numerous experiments of earlier investigators indicated at least one testicular hormone, but efforts to isolate it remained futile for many years.

The discovery by Pézard⁵¹ in 1911 of the capon as a quantitative biological test animal for androgens was a fundamental step forward. Pézard injected extracts from the testes of crypt-orchid pigs twice weekly for five months into a cockerel that had been castrated two months earlier and showed castration atrophy, and found that one tenth of a cryptorchid hog testis would produce an increase in the size of the comb and the wattle of this capon as compared with similar control birds. However, the omission of detail in his report prevented repetition and confirmation of his experiments.

McGee,⁵² in 1926, working in the laboratory of Koch in Chicago for his doctor's dissertation, was the first to prepare a lipoid extract from fresh bull's testes, 0.01 mg. of which would restore the atrophic comb of a capon. He thus confirmed an endocrine function of the testis. Three years

later Loewe and Voss,⁵³ of Mannheim, reported before the Academy of Sciences in Vienna that an extract obtained from 3.6 liters of urine from normal men would restore the castration effects of the seminal vesicles of a mouse.

Moore and his collaborators,⁵⁴⁻⁵⁸ of Chicago, in a series of studies, investigated for many years the physiologic action of testicular extracts, and not only defined the rat unit but also performed tests on spermatozoon motility, on electric ejaculation in guinea pigs and on the cytology of the prostate, the seminal vesicles and the vas deferens of the rat. Heller,⁵⁹ in 1930, studied the effects on Cowper's gland, and Binet and Luxembourg,⁶⁰ of Paris, in 1939 found that the female Xiphophore, an aquarium fish, produced a characteristic male caudal fin when injected with male urine twice weekly for six weeks. Moore and Price,⁶¹ in a classic study, presented the most adequate exposition of the interrelations between the anterior-pituitary gland and the testes.

During these years progress was rapid. In 1931, Butenandt,⁶² of Danzig, succeeded in isolating in crystalline form 15 mg. of two chemically pure substances, "androsterone" and "dehydroandrosterone," from 15,000 liters of male urine by the Funk-Harrow⁶³ method. He found that these substances were sterols of the probable formulas, $C_{16}H_{26}O_2$ or $C_{19}H_{30}O_2$, and that they were closely related to the female hormone "estrone." Ruzicka and his associates,⁶⁴ at the Polytechnic Institute in Zurich, were impressed by the similarity of Butenandt's formula for androsterone to that of cholesterol. They attempted to produce, and promptly succeeded in doing so, a synthetic crystalline compound of the same formula as Butenandt's androsterone. They evolved the process which is now used for the commercial synthesis of androsterone and testosterone by the degradation and hydrogenation of epicholesterol.

At about the same time, chemists were engaged in the laboratory of Laqueur in Amsterdam in similar work. In 1935, David et al.⁶⁵ announced the isolation of a crystalline substance, "testosterone," from bull's testes, just before Ruzicka's laboratory⁶⁶ synthesized it. This testosterone was many times more potent than the androsterone of Butenandt, and differed from it chemically by the reduction of the keto radical at carbon atom 17. Up to the present time more than thirty substances of male-hormone character, but of different degrees of physiologic activity, have been prepared synthetically by the degradation of sterols. Essentially there are two types, a saturated and an unsaturated series. Koch,^{67, 68} in 1937 and in 1939, has given the most comprehensive exposition of the chemistry of these androgenic substances. The

following excerpt will best convey the chemistry involved:

A consideration of androsterone and its closest isomers . . . shows that the *cis* configuration of the OH on carbon atom 3 with reference to the H on carbon 5 is very important providing the H on carbon 5 is *trans* to CH₃ on carbon 10. If the H on carbon 5 is *cis* to the CH₃ on carbon 10, as it is in the derivatives from coprosterol and epi-coprosterol, the physiological activity is negligible. The importance of the configuration about carbon 3 is again shown when the 17-keto group is reduced as in the androstanediols. Note that reduction of the 17-keto group in androsterone and *trans*-androsterone (dehydro-iso-androsterone) increases the potency. In other words, the 17-position secondary alcohol group is even more important than the 3-epi-OH (3-*trans*-OH) form in determining potency. If both 3 and 17 positions are oxidized to ketones, as in androstanedione, there is not much change from the androsterone potency.

The discussion above covers the saturated series. In the unsaturated series the conversion of the 17-keto group into a secondary alcohol may alter the activity slightly, but not as much as in the saturated series. . . . Comparison of the unsaturated with the saturated di-ketones does not reveal a striking effect unless the unsaturated group is between carbons 1 and 2; then the unsaturation produces a striking loss of potency. . . . Conversion of carbon 17 into a tertiary alcohol with the -OH kept *trans* also increases the potency somewhat. It appears then that the most favorable arrangements for high potency known thus far are found in testosterone and 17-methyl (*cis*) testosterone.⁶⁸

Male hormones and their derivatives are therefore sterols related to those found in the bile acids, adrenal cortex, cardiac glucosides and the digitalis sapogenins. They are closely related to some vitamins and to the carcinogens. Androgenic substances have been isolated from urine, feces and the adrenal glands. The urine of normal men and women contains androsterone and dehydro-iso-androsterone (Tscherning⁶⁹ and Butenandt and Tscherning⁷⁰) in rather large quantities as compared with the low titers found in the tissues.

Although male hormone was isolated and synthesized in a comparatively short time, there was not such progress in the determination of its sources in the testicle. The interstitial cells, first described in 1850 by Leydig,⁷¹ then professor of histology at Würzburg, and since identified by his name, are commonly believed to be the elements that produce this hormone. This view was first advanced in 1896 by Reinke,⁷² who described certain crystalloids in these cells, now known as the "Reinke crystalloids." Ance! and Bouin⁷³ from 1903 on devoted numerous papers to the study of these cells. They introduced the term "interstitial gland" to denote the secretory function of these cells, and argued strongly in favor of their being the source of male hormone. Steinach,⁶⁹ in 1912,

coined the name "puberty gland"; he⁷⁴ believed that it not only secreted the androgens, but could also be rejuvenated by vasoligation, a concept which became very popular for many years. Bouin,⁷⁶ in 1931, advanced additional evidence to prove that the interstitial cells were the producers of the testicular hormone.

This hypothesis, however, has been greatly contested, and is still not generally accepted. Furthermore, McCullagh, alone⁷⁶ in 1932 and with his associates⁷⁷ in 1935, presented some evidence that the testis may also secrete a second hormone, "inhibin," which inhibits the activity of the pituitary gland. Although the presence of the inhibin principle has been denied by some authorities, there still remains some good evidence in its favor. However, further experimental studies are needed to settle this question, which is mentioned here merely for its historical interest.

* * *

In conclusion, it can be stated that the testis was the organ first suspected of, and associated with, an internal secretion. It was likewise the first gland subjected to animal experimentation. Yet, in spite of this, approximately a century—from 1848 until 1935—was needed before the androgenic hormone was isolated and synthesized in pure crystalline form. This fact is still more surprising when comparison is made with the internal secretions of other glands, such as the thyroid, the parathyroid, the pancreas and the adrenals, whose endocrine activity was not suspected until much later, yet whose active principles were isolated chemically, and even synthesized, much earlier than were those of the testis.

With the chemical isolation and synthesis of the androgens a period has been reached in which they are studied in relation to the general metabolism of the body and to the other endocrine glands, especially the pituitary and the adrenal cortex, and in which they are applied therapeutically in several clinical syndromes. This work already commands a huge literature, but concepts are still indefinite and need more study to permit final conclusions.

In order to recapitulate the history of the discovery and isolation of male hormone, it is appropriate to present the high lights of this interesting chapter of endocrinology in a chronological tabulation:

- 1400 B. C. The *Ayurveda* of Susruta recommends testis tissue as treatment for impotence.
- 460-370 Hippocrates uses the word "hormone" for certain ferments.
- 384-322 Aristotle describes castration effects in birds, beast and man.

- 40 A.D. Matthew mentions in his Gospel eunuchs made by God (congenital) and by man (castrated), and thus furnishes the basis for the self-mutilation of the Skopets sect of Russia.
- 150 Aretaeus, the Cappadocean, in his description of gonorrhea suggests that the semen is the basis of the characteristics of the male.
- 131-201 Galen of Pergamus knows of the pituitary and believes that it secretes a "phlegm" into the nose.
- 777-837 Johannes Mesuë, the Elder, prescribes testicular extract as an aphrodisiac.
- 1543 Vesalius describes the anatomy of the pituitary gland and coins its present name.
- 1664 Willis believes that the blood receives certain ferments from the spermatic veins that make it vigorous and lively.
- 1666 John Smith uses the word "hormetick" for certain muscular metabolic products.
- 1745 Heberden's *Antitheriaka* leads to the purification of the "filth" pharmacopocias.
- 1762 John Hunter transplants the gonads of one sex into the other sex, but his experiments are not successful.
- 1775 Théophile de Bordeu argues in favor of internal secretions from some glands.
- 1801 Legallois finds that venous blood varies according to the organs from which it comes.
- 1817 Broussais points to the close association of blood vessels with the adrenal, thyroid and thymus glands and the spleen.
- 1823 Béclard shows the close relations of blood vessels to the pituitary gland and the pineal body.
- 1834 Johannes Mueller differentiates between glands with and without excretory ducts.
- 1843 Claude Bernard demonstrates glycogenesis and glycogenolysis as functions of the liver.
- 1848 Arnold Berthold performs the first successful testicular transplants in capons and thus proves an endocrine function of the testes.
- 1850 Franz von Leydig describes certain cells in the testis, which are now known as the "Leydig interstitial cells."
- 1855 Thomas Addison publishes his classic monograph on adrenal disease, known now by his name.
Claude Bernard introduces the term "internal secretion."
- 1889 Brown-Séquard publishes his famous paper on self-rejuvenation after treatment with testicular extracts.
- 1896 Reinke describes the crystalloids of the interstitial cells, now bearing his name, and suggests that these cells secrete the male substances.
- 1903 Ancel and Bouin introduce the term "interstitial gland" to indicate the secretory function of the interstitial cells.
- 1905 Starling introduces the term "hormone" for all internal secretions, as known today.
- 1907 Tandler and Grosz describe the skeletal changes found in eunuchs and Skopets after pre-pubertal castration or self-mutilation.
- 1909 Pende introduces the term "endocrinology" for the science of internal secretions.
- 1911 Pézard discovers the capon comb and wattle growth as a test for male-hormone determination.
- 1912 Steinach coins the word "puberty gland" and suggests that it can be rejuvenated by ligation of the vas deferens, a procedure now known as the "Steinach operation."
- 1926 McGee produces a lipoid extract from bull's testes.
- 1929 Loewe and Voss produce an androgenic extract from urine.
- 1931 Butenandt isolates crystalline androsterone and dehydroandrosterone from male urine.
- 1934 Ruzicka and his assistants synthesize androsterone, and later also testosterone.
- 1935 David and his associates, in Laqueur's laboratory, isolate crystalline testosterone from bull's testes.

MILITARY DISCHARGE FOR INADEQUACY*

Report of 182 Cases

CAPTAIN DAVID J. FLICKER, M.C., A.U.S.,† AND MAJOR OLON H. COLEMAN, M.C., A.U.S.‡

CAMP BLANDING, FLORIDA

MEDICINE is not yet an exact science. Army induction boards labor under difficulties that frequently increase the margin of error. They are compelled to work under great pressure, the time allotted is sadly inadequate, and there is often a shortage of trained specialists.¹ Moreover, it is impossible in one examination to weed out all those physically and psychically unable to perform as soldiers. Thus, unqualified men are occasionally placed in uniform. Unfortunately, this does not make them soldiers.

Army regulations provide for the discharge from the Service of these unfit persons. Those who fail because of organic disease or from psychoneurosis or psychosis are released under regulations providing for a certificate of disability for discharge.² This procedure we have outlined elsewhere.³

Under further regulations (so-called "Section VIII cases"),⁴ "when an enlisted man (1) is inept, or (2) does not possess the required degree of adaptability for military service, or (3) gives evidence of traits of character or habits which serve to render his retention in the service undesirable, or (4) is disqualified for service physically or in character, through his own misconduct," steps are taken to separate him from the service. This is not done, however, "until every reasonable effort has been made to develop the enlisted man concerned into a soldier." Further, every consideration must be given to the advisability of transferring the enlisted man to another organization of the regiment or post in order that he be given every opportunity to develop into a soldier. This does not apply to enlisted men who show undesirable habits or traits of character.

In most cases the discharge given is the "blue" discharge from the Army of the United States. This is neither honorable nor dishonorable; it is a discharge without honor. Exceptionally, an honorable discharge is given when the conduct of the enlisted man during his enlistment has been such as would render his retention in the service desirable were it not for his inaptitude or lack of required aptitude for military service. In these cases the certificate must show that retention is warranted. No discharge papers may be given for the reason for the discharge.

We have collected all these discharges, issued through the Station Hospital at Camp Blanding, Florida, for its first year, from November 5, 1940, to November 5, 1941.

The military personnel of this camp consisted of two divisions, the Thirty-First or Dixie Division, made up of troops from Florida, Louisiana, Mississippi, Alabama and Georgia, and the Forty-Third or New England Division, made up of troops from Maine, New Hampshire, Vermont, Rhode Island, Connecticut and Massachusetts, the Seventy-Fourth Field Artillery Brigade, composed of National Guard units from Georgia and New Hampshire and of men from the Regular Army, and the Corps Area Service Command troops from varied sources. The average camp population, subject to marked fluctuation, was approximately 30,000, ranging as high as 45,000 and at times dropping as low as 5000.

The total number of men discharged for inadequacy was 182. On the basis of an average camp population of 30,000 this is 0.6 per cent.

The following factors entered into the making of these decisions and must be considered in the appraisal of the statistics. The first factor is the difficulty in making many officers newly on active duty conform strictly to the necessary tedium of Army regulations; for this reason, many such cases have been overlooked. The second factor is the probability that many of these cases have been diagnosed as being due to organic disease. Too many physicians still refuse to recognize the frailty of the psyche because of overconcentration on the weakness of the soma. "If a man says he has a pain, how can you know he hasn't a pain?" Undoubtedly many diagnoses of sacroiliac sprain, mild heart disease, enuresis, flat feet, spastic colon and similar diseases should have been included in this group. And, finally, the board which must recommend discharge is composed of officers from the enlisted man's own company. Too often in National Guard divisions they have known the soldier at home. They are therefore inclined to doubt that he is a psychiatric case, or if they accept the diagnosis, they may be reluctant for personal reasons to discharge him on this ground. For all these reasons we believe that the number of discharges mentioned above is far below the actual number of cases warranting such action.

HOSPITAL DAYS OF CASES OF INADEQUACY

The 182 discharged men spent a total of 7405 days in the Station Hospital, for an average of 40.7 days per man. Their hospital admissions totaled 309 (Table 1). In the same period for

TABLE 1. *Hospital Admissions.*

No. of Admissions per Man	No. of Men	Total Admissions
One	90	90
Two	60	120
Three	19	57
Four	5	20
Five	2	10
Totals	182	309

the entire camp a total of 286,592 hospital days were required for all pathologic conditions encountered; these included an epidemic of influenza and an epidemic of measles. Thus, 2.6

FIGURE 1. *Duration of Service Prior to Discharge.*

per cent of the total number of hospital days were utilized by the group of 182 cases under discussion.

It must be pointed out that only 16 of the 309 diagnoses with which these men entered the hospital carried any note regarding mental observation. In all other cases the men were ad-

mitted for organic complaints. Much of the time lost was on wards where such complaints were investigated and ruled out. The neuro-psychiatrist was called in only as a last resort.

TIME REQUIRED FOR RECOGNITION OF CONDITION

The period of time from induction until the condition leading to discharge was finally diagnosed varied from five days to eleven months (Fig. 1). It will be noticed that only 10 of the 182 men lasted in the service longer than six months, and that the peak for recognition

FIGURE 2. *Geographical Distribution by States.*

The unshaded blocks represent men from urban areas; the shaded ones, men from rural areas.

of the discharge condition was three months. This is probably a longer time than will be needed for recognition in the future. In the formative period of the camp, inept and unadaptable men were not subject to the same strain and surveillance as they will undergo henceforth.

GEOGRAPHIC DISTRIBUTION OF DISCHARGED MEN

The discharged men were classified by Army divisions, by states of origin and by their previous environments, rural or urban. The Dixie Division contributed 112 (0.62 per cent) of its total manpower of 17,942 soldiers, the New England Division 53 (0.32 per cent) of its 16,483 soldiers, and other units 17 men. These figures do not seem to reflect any differences in the caliber of the men from various parts of the country. A probable contributing factor was the fact that New England induction boards were somewhat more

efficient in weeding out subnormal material than those in other sections.

On the basis of figures given in the 1941 *World Almanac*, we listed all residents of towns of 2500 population or over as urban, and divided the discharges accordingly into rural and urban. We found that 70 (38 per cent) came from urban

engineers, and 12 were from the hospital medical detachment. Exact percentages cannot be given, but it is certain that the smallest incidence occurred in the infantry, the next in the artillery, the next in the engineering corps, and the highest in the hospital detachment. This indicates that the more technical the work required, the greater the

FIGURE 3. Age at Discharge.

communities and 112 (61 per cent) from rural communities. Figure 2 shows the preponderance of rural cases from the South. This is attributable to the predominance of farming as an occupation in that area. In a random sample of 3000 soldiers, 68 per cent came from rural and 32 per cent from urban areas. Therefore, much to our surprise, more city men proportionately were found inept or otherwise inadequate for military duty. This finding is diametrically opposed to the one we described in an earlier paper.³

AGE DISTRIBUTION

The age distribution of the men discharged (Fig. 3) was roughly parallel to that of the camp personnel as a whole. It demonstrates that inaptitude affects the same percentage of each group and that experience and increasing age do not enable the men to outgrow their difficulties. When the most frequent diagnoses, constitutional psychopathic state and mental deficiency, are considered this statement does not seem brash.

DISTRIBUTION BY TYPE OF MILITARY SERVICE

Of the 182 men discharged, 121 were infantrymen, 41 were from the field artillery, 8 were en-

likelihood that inaptitude will be revealed. The large number from the hospital detachment is especially significant. Possibly working in the hospital educated these men in the ways and means of successfully simulating the constitutional psychopathic state. The incidence in this group was several hundred per cent higher than that to be expected in the other types of military service. This suggests that henceforth an additional check should be placed on those in similar positions.

DISTRIBUTION BY RANK

The distribution by rank (Table 2) was as follows: 170 men were privates, only 6 were noncom-

TABLE 2. Distribution by Rank.

RANK	NO OF MEN DISCHARGED	PERCENT- AGE DIS- CHARGED	PERCENTAGE OF RANK IN THE ARMY
Private	170	93	52
Private, first class . .	6	3	30
Corporal	2	1	10
Sergeant	4	2	8
Total	182		

missioned officers, and only 6 were first-class privates. The extremely low proportion of first-class

privates, corporals and sergeants to privates, in comparison with the ratio in the Army as a whole of one noncommissioned officer to every four privates, shows that most company commanders made promotions wisely.

DISTRIBUTION BY OCCUPATION

Classification by occupation previous to military service (Table 3) was arbitrary. Each case was

TABLE 3 *Distribution by Occupation*

TYPE OF OCCUPATION	NO. OF MEN DISCHARGED	PERCENT ALL DISCHARGED	PERCENT IN THE ARMY*
Unskilled	105	58	28.7
Semi skilled	32	18	23.1
Skilled	19	10	20.2
Business	12	7	18.4
Professional	4	2	9.6
Never employed	10	5	0

*Based on 3000 soldiers

considered on its merits and given the full benefit of doubt; that is a higher rating was given whenever the question arose. Thus, store clerks were listed under "business," and truck drivers as "semi-skilled labor"; of the 4 men listed as "professional," two were students (exact status unknown), one was a Salvation Army fieldworker, and the last was a chiropractor. We admit that our generosity in rating is open to question; yet the occupational status of the series runs quite in accord with the expectation, the greater number of men being in the lower socioeconomic groups prior to induction.

DIAGNOSES

Mental deficiency was the reason for discharge in 67 cases. The Kent E G Y test was used as a standard and was supplemented by other tests whenever indicated. The mental ages are shown in Table 4. Almost all these cases were said

to show the "hypochondriasis of oligophrenia." Each presented multiple organic syndromes that required intensive investigation. Only when these had been disproved in the gastrointestinal, cardiac, urologic or other wards and much valuable time

had thus been spent did they finally reach the neuropsychiatric section.

Two men were discharged with a diagnosis of neurasthenia, gastrica. These diagnoses were probably erroneous, since it has been suggested by the Surgeon General's Office that such cases should receive a diagnosis of psychoneurosis, conversion hysteria. However, since these men were discharged under Section VIII they have been included in our series.

The rest of the men were discharged with a diagnosis of constitutional psychopathic state. This condition is classified by the *Standard Diagnostic Book* of the United States of America in seven groups: inadequate, paranoid, emotionally unstable, criminalistic, pathological liars, sexual psychopathy and unqualified. Of these, only three were used as the primary diagnosis: 55 men were listed as inadequate, 48 as emotionally unstable, and 19 as criminalistic. Occasionally, they were employed as secondary diagnoses.

In every case short but reasonably adequate histories were taken. So far as possible, childhood impressions, school records, former occupational situations, court and criminal records, sexual histories and personal relationships were probed

RECOMMENDATIONS

We believe that each selectee and enlisted man, prior to his final induction into the Army, should be placed in a replacement center for a probationary period of three months. During this time a competent psychiatrist should assist the company commander in weeding out those psychically unfit for military duty before marked breakdowns occur or severe inadequacies make themselves apparent. The great majority of these cases, as well as most undetected psychoneurotic patients, could thus be eliminated without ever being actually inducted. This would save the Army the expense of many hospital days and spare the selectees the mortification of complete realization of failure.

Furthermore, this trial period should be served without prejudice to the Government, and barring physical disability incurred during it, the enlisted man or selectee should have no claim against the Veterans' Bureau. This arrangement would make possible the saving of both time and money. It would also aid materially in eliminating future compensation claims. It is impossible to estimate how many constitutionally psychopathic persons and mental defectives are now collecting government pensions because of a few months spent in an Army training camp in the last war. Judging from our experience, they spent even these few months in the hospital—their sole contribution then, as it is now—only to hinder the war effort.

SUMMARY

A report is given of 182 soldiers discharged from the Army through the Station Hospital at Camp Blanding, Florida, under Army regulations providing for the release of men who are incompetent or inept, or have habit or personality traits undesirable in a soldier.

The number of hospital days used, the time required for the recognition of inadequacy, and the distribution by geographical considerations, age,

type of service, rank, civilian occupation and discharge diagnoses are discussed.

Some recommendations are offered to aid in the diminution of the number of these cases.

MEDICAL PROGRESS

GYNECOLOGY: NEOPLASMS OF THE OVARY

JOE VINCENT MEIGS, M.D.*

BOSTON

A REVIEW of the literature concerning ovarian growths shows that a large amount of information that is not generally possessed is now available. From the confusion of great numbers of ovarian cysts, cancers and benign tumors, considerable advance has been made in simplifying classifications and placing the various lesions in their proper niches. Robert Meyer¹⁻³ and Walter Schiller⁴ have especially been in the vanguard for separating the special types from the enormous heterogeneous group of a few years ago. Many growths once considered malignant are now considered benign, and many tumors of more or less definite histology have been shown to be functioning tumors. Americans who have made special contributions to the subject of ovarian cancer and its treatment and prognosis include Lynch,⁵ Geist,⁶⁻¹⁰ Frank,¹¹⁻¹² Taylor and Greeley¹³ and Pemberton.¹⁴ In this review it will not be possible to give credit to each investigator, but many important references are appended.

In a review of the literature it is perhaps not correct to present a classification of ovarian neoplasms, but the classification given below, based on Schiller's¹⁵ recommendations, seems to simplify the whole problem.

CLASSIFICATION OF OVARIAN NEOPLASMS

It is obvious that the ovary must contain in itself many potential growth cells. It commences as a clump of mesenchymal cells on the posterior wall of the abdominal cavity behind the forming peri-

toneum. This primitive group of cells furnishes those that under certain circumstances become specialized cells, some of which may eventually be indistinguishable from epithelial cells. For instance, the primitive connective-tissue cells of the early gonad may surround an ovum and become granulosa cells or theca-interna or theca-externa cells. In contact with spermatozoa these same cells may differentiate into Sertoli cells or the supporting cells of the testicular tubule. Sometimes the cells that usually become differentiated do not change toward male or female cells, but remain neuter and develop into the cells of the dysgerminoma or neuter tumor. The undifferentiated connective-tissue cells from which the differentiating cells arise form the stroma of the ovary, and from them may arise the fibroma and sarcoma of the ovary.

The epithelial covering of the ovary, arising as it does from the celomic epithelium of the pelvis, may differentiate into epithelial-like structures similar to those that arise from the celomic epithelium. As the celomic epithelium is the precursor of the müllerian ducts, it is easy to appreciate that epithelium similar to whatever the müllerian ducts might form may be present in the ovary. The upper vagina, the cervix, the endocervix and the endosalpinx are derived from these ducts. Therefore it is possible that squamous epithelium, endocervical epithelium, endometrial epithelium and endosalpingial epithelium may be present in certain tumors of the ovary. Schiller¹⁵ has demonstrated that the pseudomucin noted in the so-called "pseudomucinous cysts" of the ovary is not pseudomucin but old changed mucin. Thus, if pseudomucin is mucin in certain mucinous cysts, it is probably

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual*, Vol. III, 1942 (Springfield, Illinois: Charles C Thomas Company, 1942. \$5.00).

*Clinical professor of gynecology, Harvard Medical School; chief of Gynecological Service, Massachusetts General Hospital.

derived from the cervical epithelium, such lesions being endocervical epithelial tumors. Simple cystadenomas, papillary cystadenomas, malignant papillary cystadenomas and solid cancers of all the above types therefore arise from the epithelium of the covering of the ovary. There is of course an unclassified group that may arise from a more primitive type of celomic cell.

Inasmuch as the primitive ovary grows in close proximity to the adrenal gland, the kidney and the primitive mesonephros and wolffian ducts, it is not surprising that tumors of these types are occasionally found in the fully formed ovary. Cells of organs arising near the ovary are incorporated in it during its growth and develop early or later in life. Thus the origin of the adrenal cell tumor of the ovary and the mesonephroma and Brenner tumor is explained.

The ovary contains ova, and if one of these should be fertilized, either parthogenetically or otherwise, the ovary would probably contain tumors or cysts of cells from all other organs or tissues of the body. These growths when solid and made up of undifferentiated or differentiated cells are called teratomas, whereas the cystic types as a rule contain all three germ layers and are known as dermoid cysts. Thus the fertilization of an ovum in an ovary may produce tumors similar to the thyroid gland, cartilage, bone, the central nervous system, the intestinal tract or any part of the epithelial system. A tumor of intestinal epithelium in a dermoid cyst can easily explain certain other of the so-called "pseudomucinous tumors," which are really mucinous tumors. Pseudomucinous peritonitis arises from these tumors, but in both men and women it may be present in patients with mucocoeles of the appendix. It is probable that the origin of such peritonitis is the mucus cells of the intestinal tract.

The ovary is also the seat of metastatic lesions. Tumors of the stomach metastasize to the ovary and are responsible for Krukenberg tumors, which are myxomatous in type and contain signet ring cells that secrete mucus. Endometrial cancers of the uterus metastasize to the ovary, and these tumors cannot be differentiated from malignant epithelial tumors of the ovary formed from the primitive endometrial cells of the celomic epithelium. Thus there are two types of endometrial cancers of the ovary, one formed from the covering of the ovary and one metastasizing to it from the uterus. Other organs of the body may be responsible for metastatic tumors in the ovary—small intestine, bile duct, breast, large intestine, rectum and even the pigment cells of the eye.

Thus it is clear that neoplasms of the ovary may be grouped into those arising from the celomic epithelium covering the ovary, from the

primitive mesenchymal cells, because of continuity and from fertilized ova and those metastasizing to it. The classification is as follows:

- Tumors arising from celomic epithelium (vaginal, endocervical, endometrial, endosalpingial)
 - Cystoma (endometrioma, endosalpingioma, adenoma, fibroidenoma)
 - Papillary cystadenoma
 - Malignant papillary cystadenoma
 - Solid carcinoma
- Tumors arising from primitive mesenchyme
 - Arrhenoblastoma
 - Granulosa cell, thecal cell
 - Luteoma, xanthofibroma theca cellulare
 - Disgerminoma (neuter)
 - Fibroma
 - Sarcoma
- Tumors arising because of continuity
 - Adrenal cell
 - Kidney cell (hypernephroma)
 - Mesonephroma
 - Brenner (renal pelvis, ureter or urethra)
- Tumors arising from fertilized ova
 - Teratoma, chorionepithelioma, struma
 - Dermoid cyst
- Metastatic tumors
 - From uterus (endometrial)
 - From stomach (Krukenberg)
 - From intestine (small or large), eye, rectum, breast, bile duct and so forth

These five sources include all the possible ovarian neoplasms, and such a grouping is not difficult to understand or remember. Physiologic cysts have been deliberately omitted because they are not true neoplasms but represent abortive ovarian function. Such cysts include atretic follicles, follicle cysts, corpus luteum cysts and thecal lutein cysts. These small cysts are important but should be considered in the abnormal physiology of the ovary and not among its neoplastic possibilities.

GENERAL CONSIDERATIONS

Careful and thorough investigations must be carried out in patients with ovarian tumors. Such investigations are those conducted in patients with abnormal bleeding, thyrotoxicosis, hirsutism, virilism, fluid in the abdomen and chest and increase or decrease in size of the breasts. One must be familiar with the technic of endometrial biopsy and peritoneoscopy. Laboratories must be available to determine the levels of follicle stimulating hormone, estrin and pregnandiol, to measure the basal metabolic rate, to perform Aschheim-Zondek and Friedman tests and to determine the excretion of the androgens and 17 ketosteroids—the latter being a representation of adrenocortical function.

It must be remembered that at operation a pathologist should be present who can help to de-

termine the type of tumor with which one is dealing. It is essential in modern surgery to be able to distinguish benign from malignant tumors. Tumors that appear malignant in gross may be relatively benign; such is the dysgerminoma, whose diagnosis is made more easily from a frozen section than from a fixed section. One should also be able to make a prognosis, based on the type of tumor found. Another reason for making a histologic diagnosis before the patient's abdomen is closed is to be certain that the tumor is not one that is likely to be bilateral, or to be of such a type that might metastasize to the uterine body and thence to the cervix. It is recognized that an occasional tumor will respond well to x-ray therapy: every gynecologist has had some patient who had metastases to the omentum or to the peritoneum, with fluid in the abdomen, and who, after removal of a certain amount of the primary tumor, responded to x-ray treatment, but these cases are rare.

The new syndrome^{16, 17} of abdominal and chest fluid due to fibroma of the ovary must not be forgotten; if a patient has a tumor in the pelvis with fluid in the chest and abdomen, one must not conclude at once that the lesion is malignant. It has been shown that the removal of a simple fibroma of the ovary may cure such a condition. It is also true that cystadenomas and malignant papillary cystadenomas of the ovary may be accompanied by pleural as well as abdominal fluid. Reports have been made by MacFee¹⁸ and Dannreuther¹⁹ of such fluid in benign lesions, and by Schenck and Eis²⁰ in a malignant one. Recently a similar case was seen at the Pondville Hospital; the patient, who had a cancer of the ovary with fluid in the chest, was probably cured by removal of the ovarian tumor — there were no malignant cells in the centrifuged chest fluid.

Today, adequate knowledge demands that the surgeon recognizes the type of lesion, if possible, that he knows the proper investigative laboratory technics, and that he realizes how and when to use x-ray treatment. The last has never cured patients, but it has helped to make them live longer. It must be outlined by the roentgenologist in such a way that it is directed toward the tumor, toward the spilled portions of the tumor or toward the adhesions connected with the tumor. It is of no use for the surgeon to write a note to the x-ray department saying simply: "Carcinoma of the ovary. Please treat." This practice should be abandoned.

TUMORS ARISING FROM CELOMIC EPITHELIUM

Cystomas of the ovary are true neoplasms and arise, as postulated, from the epithelium covering the ovary. They may be small or large; they may be single or multilocular; and they may contain serous or so-called pseudomucinous fluid.

The epithelium may be of the tubal, endometrial or endosalpingial type, or even of an unclassified type. The possibility that this lesion is bilateral is great; therefore both ovaries should be examined carefully. This lesion is not malignant, and its simple removal from the ovary, if possible, or removal of the ovary itself with a careful inspection of the other ovary, is all that is necessary, but the patient must be watched.

Papillary cystadenomas present a different problem. These are potentially malignant. If the papillary growths are all on the inside of the ovary and if they are filmy and small and not infiltrating, the chances of their being benign are very great. However, they may be malignant microscopically. They are bilateral in 30 to 40 per cent of cases. One finds in these lesions the type of epithelium that grows from Müllerian epithelium — squamous epithelial, endocervical or mucinous, endometrial or endosalpingial. Proper treatment for the papillary cystadenoma is removal of both ovaries. However, because many of these occur in young women in whom the preservation of fertility is essential, one can be conservative but must watch carefully to make sure that there is no occurrence in the other ovary, which may be of the malignant type. If the pathologist finds an area that is suggestive of cancer, the responsibility of the surgeon is great. Should he reoperate and take out the other ovary? No one can solve this problem but the surgeon himself. Should he elect to reoperate and remove the other ovary, no one could criticize him.

A *malignant papillary cystadenoma* demands close scrutiny. If a papillary cyst of the ovary shows thickness of the wall, penetration through the wall of the cyst to the other side or papillary areas on the outside of the cyst, one must be very suspicious of malignancy. The pathologist cannot always assure the surgeon, but if the tumor is considered probably malignant, radical surgery should be carried out. By radical surgery is meant the removal of the uterus and the cervix, because the presence of metastases in the uterine wall means that there may be metastases in the cervix. The opposite ovary is involved in a large percentage of cases; therefore it also should be removed. The prognosis for these patients is about 21 per cent survival for five years — a very small percentage of curability. It must also be remembered that metastases from endometrial cancer are very similar to the endometrial type of malignant papillary cystadenoma. One must determine by curettage of the endometrium whether or not it is involved primarily and the ovary secondarily, or vice versa. Most surgeons believe that x-ray treatment is unnecessary if the lesion is removed in toto without spilling or with-

out evidence of adhesions. If spilling has occurred or if there are evidences of adhesions and of growth onto the bowel or peritoneum, x-ray treatment must be given; and, if so, the case must be discussed with the roentgenologist so that the x-rays can be directed in the proper direction.

Solid carcinoma of the ovary is the most serious of all the epithelial growths of this organ. The curability is very low, 9 per cent survival for five years. It is believed, however, that if the patient lives for two and a half years following removal of such a tumor, the chances of permanent cure are very great.²¹ Patients with malignant papillary cystadenoma succumb more slowly than do those with solid cancers; if the solid cancers are cured, they are usually thoroughly cured. These tumors may be made up of the squamous-cell type of epithelium, representing the vagina, the mucinous, representing the endocervix, the endometrial, representing the endometrium, or the endosalpingial, representing the inside of the tubes; or they may be of an entirely unclassified type. Abnormal bleeding is not uncommon in these lesions. It is the general belief that the peritoneoscope is of great value in diagnosing this tumor, and it should be used frequently and without hesitation to determine whether the tumor can safely be removed or whether there are metastases throughout the abdomen. In spite of the fact that the abdomen and even the liver, or at least the surface of it, may be thus involved, one must consider removing the local growth, because for some reason or other this procedure may prevent rapid growth of these extensions. Metastatic areas and fluid have been known to vanish after removal of the primary growth; why, is not known. The question of dissecting lymph nodes in patients with solid cancer of the ovary is an important one. As yet this dissection cannot be advocated, but the time may come when, if more is known about where these metastases are likely to occur, removal of them will become part of the surgical approach. X-ray treatment should be given, as in malignant papillary cystadenoma, only when it is known where the tumor has extended.

Included in this group of celomic epithelial growths are the *endometriomas* and *endosalpingiomas* of the ovary and tube. These are benign lesions growing from the epithelium of the cortex down into the body of the ovary, forming the so-called "chocolate cysts." There is a difference of opinion whether these lesions come from the endometrium itself, the cells flowing through the tubes and alighting upon the ovary at the time of menstruation, or arise from the endosalpinx, attaching themselves to the ovary, or arise from the celomic epithelium covering the ovary. It is not unlikely that the last-named source is the primary one.

These cysts grow to moderate size before they are so pressed on by connective tissue and ovarian capsule that function ceases. There is no question that the endometrioma menstruates, but how long it continues to do so is doubtful. Endometriosis of the pelvis, which may arise from an endometrioma of the ovary that has become adherent to the broad ligament or to the cul-de-sac, may be a serious lesion demanding radical surgery. However, most gynecologists believe that if one can be conservative one should excise the endometrioma from the ovaries or ligaments and save the pelvic organs so that future childbearing can take place. It is also believed that pelvic endometriosis is increasing, perhaps because of avoidance or postponement of pregnancy. Normal childbearing is most important in order to prevent the onset or growth of this lesion.²²

TUMORS ARISING FROM PRIMITIVE MESENCHYME

The *arrhenoblastoma* is male-directed and is often, although not always, accompanied by virilism, masculinization, hirsutism and so forth. The testicular tubular adenoma of Pick is the most highly differentiated type. In patients showing physiologic effect of such a tumor the clitoris is enlarged, the scalp hair recedes, and the growth of hair increases in areas similar to those found in men; the breasts atrophy, the voice becomes deeper, and the patient assumes a mannish physique. Sometimes amenorrhea accompanies this tumor, but not always. The tumor may be small or large. It is usually freely movable and is not always malignant. It has been stated that removal causes the hair to recede, but it has been the experience of the Ovarian Dysfunction Clinic at the Massachusetts General Hospital that the hair does not recede but grows softer, without further increase. The voice rarely returns to normal, because there is an anatomic change in the larynx owing to the presence of this male tumor. The clitoris does decrease in size.

The diagnosis of this lesion in those in the menstruating age is not difficult because it so frequently causes amenorrhea and the above changes in the appearance of the patient. The follicle-stimulating hormone in the urine of such patients is extremely low, and the presence of a low titer of follicle-stimulating hormone, amenorrhea, hirsutism and the presence of an ovarian tumor indicate the diagnosis. Albright²³ thinks that a low titer of follicle-stimulating hormone is of extreme importance. The amount of 17-ketosteroids in the urine, which is primarily a measure of adrenocortical male hormone, is not necessarily disturbed; it may be high but usually is not. The arrhenoblastoma as a cause of symptoms should

The granulosa-cell tumor should be grouped together with the thecal-cell tumor from primitive connective-tissue directed toward the female after very early growths, as stated, and distinguishable from early antral follicles. Granulosa-cell tumors grow in undifferentiated or differentiated form. In some tendencies of attempts at follicle formation may be thought to be present, but usually proved to be areas of degeneration, the so-called "Call-Exner bodies." No corpora are present in granulosa-cell tumors. Kuder and Cadden²⁷ suggest that these tumors arise in the granulosa cells of follicles, as Fawcett²⁸ showed, arising in x-ray treated

[illegible]

cellulare or luteinized thecoma. These tumors are rare and are usually benign. They produce definite changes in the endometrium, causing a persistent secretory phase, and are often accompanied by marked decidual formation. Amenorrhea may be present. The presence of persistent secretory endometrium and periods of amenorrhea and bleeding when an ovarian tumor is present usually clinch the diagnosis.

The *disgerminoma* was formerly called a seminoma, as was the testicular tumor of the same histologic structure, but Meyer³¹ showed that this tumor does not arise from the seminiferous tubules of the testicle, but rather has invaded them; therefore the old nomenclature had an incorrect basis and he called the growth "disgerminoma." *Dis* means "both"¹⁵; that is, the same type of neoplasm occurs in the male and the female. In the male it is considered extremely malignant, whereas in the female it is frequently benign. Seegar³² says that the disgerminoma has a mortality of 35 to 60 per cent, basing his conclusion on 50 cases from the literature and on the results of treatment in 17 of 19 cases in his report. Of the 12 cases seen at the Massachusetts General Hospital, only 1 has proved to be malignant, and in that case the tumor had already begun to invade the surrounding tissue.

The disgerminoma is neuter; it arises from those primitive cells that might have developed into either granulosa or Sertoli cells but did not. It has no endocrine function. A large number of cases have been reported. The lesion can be recognized on frozen section as easily as from a fixed section. The tumor is made up of large round cells divided by connective-tissue-cell septa full of lymphocytes, and the presence of foreign-body giant cells is common. Disgerminomas were formerly called large round-cell carcinomas of the ovary; they were given x-ray treatment, and were frequently cured. The tumor is very radio-sensitive, but it is also benign in the majority of cases, and therefore x-ray treatment should not be given, because some of the young patients might otherwise be able to have children. Many times the patient herself is a neutral, that is, her genital tract is not normally developed. In many of the cases at the Massachusetts General Hospital, however, there was normal female development. Moehlig³³ reports a case of intersexuality in a patient with malignant teratoma of the seminoma type. He was probably describing a disgerminoma, and possibly one that arose in an ovario-testis. Long et al.³⁴ report a disgerminoma in a pseudohermaphrodite. Among the cases at the Massachusetts General Hospital was that of a young girl of seven, with pubic hair, open vagina and a large clitoris. Pregnancy occurred in 3 pa-

tients following removal of the tumor. These tumors are supposed to be common in the ovario-testis. The ovario-testis itself is a rare lesion, not being a tumor but a physiologic abnormality, the gonads being made up of both ovary and testis.

Fibromas of the ovary arise from the non-differentiating mesenchyme that is to become the stroma of the ovary. They are not uncommon. The size of the tumor varies from that of a small pea to that of an adult's head. It may grow on the outside of the ovary in papillary fashion or may include the whole ovary. Usually there is a firm capsule, and on section the tumor shows whirling areas of connective tissue as in uterine leiomyoma. It is well known that the condition is often accompanied by abdominal fluid. Recently Meigs and Cass³⁵ presented a number of patients with fibroma of the ovary with fluid in the chest as well as in the abdomen. Up to the present time 27 cases with fluid in the abdomen and chest have been reported in the literature.¹⁶ The fluid may be in the right or left chest, or in both. The reason for its occurrence is unknown. Probably the fluid is formed in the abdomen and enters the chest cavity by way of the diaphragmatic lymphatics. This entity is important because patients who have an ovarian tumor with fluid in the chest and abdomen do not necessarily have a tumor that is malignant and has metastasized to the chest. Chest taps with centrifuging of the fluid and examination of the cells is extremely important, because if no malignant cells are present one may be dealing with a fibroma of the ovary, and its removal will stop formation of fluid in the chest as well as in the abdomen. Reports are already appearing in the literature of patients who were given up as hopeless but were relieved by surgical removal of the benign lesion. Ovarian cysts have been reported with the same findings, as have leiomyomas of the uterus. It must be remembered that ascites alone can occur with any large benign pelvic tumor.

Sarcoma of the ovary is rare and arises from the same primitive undifferentiated cells that form the stroma. Patients with true sarcoma do not do well and the prognosis is poor. If the diagnosis is made, removal of both ovaries is best. Removal of the uterus is not essential in these cases, since it is rare for metastases to occur there. Reclassification of sarcomas of the ovary in the laboratory has in many cases proved them to be other types of tumors.

TUMORS ARISING BECAUSE OF CONTINUITY

The *adrenocortical-cell* tumor is among the group arising from continuity. Inasmuch as this part of the adrenal gland contains a male-directed hormone, such a tumor in the ovary may produce

masculinization, hirsutism and so forth, just as may an adrenocortical cancer, tumor of hyperplasia. Novak³⁶ has recently reported 3 patients with adrenal-cell tumors of the ovary with masculinization. Clear-cell tumors of the ovary, so often considered as adrenal, are not necessarily of the masculinizing type, nor are they necessarily adrenal. They may be clear-cell carcinoma of the kidney, the *hypernephroma*. This tumor is not accompanied by any definite symptoms. Van Kirk and Edwards³⁷ describe a hypernephroma of the ovary. A patient with a functioning adrenal-cell tumor of the ovary may become masculinized with male configuration, hair, large clitoris, change in voice, amenorrhea and so forth. There may or may not be a change in the sugar metabolism, but one would certainly expect it. There should be an increase in the excretion of 17-ketosteroids. The presence of an ovarian tumor accompanied by the above symptoms should be investigated by all available laboratory methods, and differentiation from an arrhenoblastoma is difficult unless the 17-ketosteroids and the sugar curve are estimated. If the 17-ketosteroids and sugar metabolism are upset, the adrenal glands should be explored by air injection and an intravenous pyelogram. If nothing abnormal is found, surgery should be undertaken, and there are definite possibilities of finding an active adrenal tumor.

The *mesonephroma*, which Schiller³⁸ has described, contains primitive glomeruli and probably arises from the primitive kidney or mesonephros. It occurs in the ovary because of the closeness of the mesonephros to the primitive gonad. These tumors are probably benign, and conservative treatment is usually the method of choice; however, Rosenblatt and Grayzel³⁹ have recently recorded a malignant mesonephroma.

Tumors of the *Brenner* type probably arise from the type of epithelium that is present in the kidney pelvis, ureter and urethral orifice.⁴⁰ Small clumps of stratified transitional epithelium are found in areas in the ovary, which has the appearance of a fibroma. Novak and Jones⁴¹ believe that Brenner tumors arise in the Walthard islands of indifferent cells in the ovary, and that the epithelium cells of the Brenner tumor may develop into pseudomucinous cells and later form pseudomucinous cysts. The Brenner tumor is found along with the so-called "pseudomucinous cystadenoma," and it is possible that this lesion might arise from a teratomatous development. The epithelium, however, is probably representative of the epithelium of the urinary tract.

TUMORS ARISING FROM FERTILIZED OVA

The fertilized ovum in the ovary may produce any sort of tumor or cyst. The ovum is considered as fertilized parthenogenetically, or the tera-

toma may be considered as a twin of the host. Fertilization occurs in some manner that we cannot explain. Shaw⁴² does not believe in the parthenogenetic theory but thinks that teratomas may arise from some functioning sex cell. He supports his belief by stating that most teratomas are formed of adult cells; if they were to arise from a fertilized ovum there should be a trophoblast, but there is none. He concludes that he does not know the origin of these tumors.

The *teratoma* is usually solid, composed of one type of tissue, such as thyroid, nerve tissue, cartilage and so forth, although Smeltzer⁴³ reports a solid malignant teratoma with three germ layers. The cells may be primitive and unrecognizable as being of any particular type, and in some cases are so undifferentiated as to be called embryonal. This represents the most primitive type of teratoma. Teratomas may or may not be malignant. They may invade and metastasize. If definitely malignant, radical surgery should be undertaken, with removal of the other ovary, the uterus and the cervix. If the malignancy is doubtful, radical surgery is still the best procedure.

Dermoid cysts are highly differentiated types of teratomas made up of two or three of the germ layers and often containing nerve tissue, skin, hair, teeth, bone, cartilage and so forth. Some of these lesions are malignant; most are benign. It is possible for a dermoid cyst to show malignant-looking areas and yet be a benign lesion. This picture is similar to what one sees in the parotid-gland mixed tumors, where there may be the most active-appearing carcinoma, and yet if any cartilage is found in the same tumor it is usually a locally malignant lesion only. Such a tumor will recur, but will not metastasize. Dermoid cysts with malignant areas act in the same way; that is, they may be malignant in appearance only, but they can be and sometimes are extremely malignant. The usual treatment of the simple dermoid cyst is excision with the ovary or excision from the ovary. About 8 per cent of these cysts are bilateral.

Chorionepithelioma of the ovary must be considered as a teratoma. Simard⁴⁴ has recently seen 2 cases of chorionepithelioma and believes in its parthenogenetic origin. Such a lesion would of course give a positive Aschheim-Zondek test, being composed of chorionic tissue. The chorionepithelioma is occasionally extremely malignant.

In the teratoma group there may be pseudomucinous cystadenomas arising from epithelium similar to the epithelium of the small intestine. Such a tumor is similar in appearance to the pseudomucinous cystadenoma of the endocervical type described above. The presence of hair or cartilage in such a cyst places it in the teratoma group.

Otken⁴⁵ has recently reported a primary mel-

anotic sarcoma of the ovary. This rare lesion is probably of teratomatous origin.

Struma or thyroid tumors of the ovary are not very rare and may include the whole tumor or a small area in a cystic growth. The thyroid tissue appears to be normal, and its iodine content is the same as that of normally placed thyroid tissue. Emge¹⁶ believes that 5 per cent of these tumors are toxic, and he reports a typical case. He quotes other authors with apparent authoritative cases. These tumors are usually benign but may be malignant.

METASTATIC TUMORS

The commonest metastatic tumor of the ovary is that due to the metastasis of *endometrial cancer*. There is often difficulty in recognizing whether this metastasis has occurred, or whether the endometrial type of cancer in the ovary is primary there, growing from the celomic epithelium. It is important, therefore, to curette patients with ovarian cancer in order to be sure that there is no cancer in the endometrial cavity. It has been the experience of most surgeons that involvement of the ovary from endometrial cancer indicates a very bad prognosis.

The *Krukenberg tumor* of the ovary, a metastatic tumor, is usually bilateral and smooth and has a thick capsule. On section it is myxomatous and suggests sarcoma. There is considerable controversy whether or not there is such a thing as a primary Krukenberg tumor of the ovary, there may be, but such a lesion should be considered a teratoma. Certainly the usual tumor is metastatic, the primary tumor being in the stomach. They arrive in the ovary by way of the retroperitoneal lymphatics and the lymphatics of the mesosalpinx, mesoovarium, uterine wall and tube, and are usually full of cancer cells. The gastric cancer cells do not float down to the pelvis, alight upon the ovary and then grow. This type of growth is not papillary on the outside of an ovary but is smooth and symmetrical and has obviously grown from the inside of the gonad.

Tumors of the small intestine metastasize to the ovary, and although similar in gross to Krukenberg tumors are frequently adenocarcinomas. Those metastasizing from the large bowel and rectum are of the same type as the primary ones; they are usually unilateral. In patients with widespread lesions of the breast or of the bile ducts, involvement of the ovary is not uncommon, but it is rare to find a tumor of the real Krukenberg type, that is, bilateral, large, smooth tumors. The metastasis of breast cancer to the ovary is usually a terminal finding. If, at operation, tumors of the ovary are found that are bilateral, smooth and kidney shaped, a primary source in the stomach

or intestine must be searched for. There are tumors from other sources that may metastasize to the ovary, such as melanoma of the eye, cancer of the cervix or tube and so forth.

SUMMARY

This discussion of ovarian tumors demonstrates that more tumors have been grouped together and that a simpler classification is possible. Many tumors of highly specialized types have been removed from the large group of ovarian tumors and more appropriately reclassified. Functioning or endocrine tumors have been recognized.

The treatment of certain ovarian lesions is definite and may be conservative, but the proper treatment of malignant ovarian epithelial growths is by means of radical surgery, with removal of both tubes, both ovaries, the uterus and the cervix. It is important to recognize that the other ovary should be removed in malignant papillary cystadenoma or solid cancer because of the large percentage of these tumors that are bilateral, and that the uterus and cervix should be removed because of the possibility of metastases into the uterus and thence into the cervix.

It has been demonstrated that x-ray treatment is not too successful and must never be allowed to influence the surgeon as against radical surgery. Roentgen ray treatment will prolong life but will not cure the patient. It has been obvious in all clinics that the x-ray treatment given in the past has not necessarily been given over the area of the extension of the growth. It is extremely important that the roentgenologist be shown by the surgeon where the tumor has been left behind or spilled so that the x-rays can be properly directed.

Knowledge of the pathology and histology of these tumors is of great importance. The presence of a pathologist at the operation is essential, for an expert can often differentiate one type from another. Thus the pathologist can help in the decision of whether or not to be radical.

If a mistake has been made and an ovary left in that might be involved, either because the tumor is often bilateral or because of the chances of a metastatic lesion, it is better to reoperate than to risk x-ray treatment. X-ray treatment should not be used to replace radical surgery.

Ovarian tumors are now receiving the attention of the endocrinologist and the medical man as well as the surgeon and the pathologist, which is well. The presence of functioning tumors of endocrine type has greatly increased the interest in all ovarian tumors. Special tests and special methods of investigation are now undertaken in patients who have abnormal physiologic responses possibly due to a tumor of the ovary.

means cancer. Tuberculosis, bronchiectasis and lung abscess may cause streaked sputum intermittently. A constantly bleeding process is usually due to a growing and friable tumor.

The complaint of chest pain favors cancer. Although an abscess with pleural inflammation gives pain, it is rarely so constant and severe as indicated here.

At this point, on the basis of history alone, I should make a presumptive diagnosis of cancer. What additional evidence must we examine?

The age of the patient favors cancer. His sex gives at least a four-to-one chance in favor of the diagnosis.

Physical examination only confirms what we suspect. The chest signs are consistent with an inflammatory process in the left lower lobe. The absence of a wheeze is not necessarily disturbing. A persistent wheeze always means a bronchial obstruction, but wheeze may be absent in varying degrees of blockage. Palpable axillary nodes in an elderly emaciated patient can be given no weight.

The laboratory was noncommittal. There was a mild degree of anemia, and a slight leukocytosis. Negative but weighty evidence is given by the sputum reports, on the basis of which I have excluded tuberculosis.

May we have the x-ray films?

DR. JAMES R. LINGLEY: Here is the cavity described lying in the middle of the left lung field. Its walls are thin and smooth, and there is a well-defined fluid level in its upper third. In the lateral view, the cavity is seen to lie posteriorly and to occupy the apex of the lower lobe. A Bucky film shows no evidence of rib or spine involvement, the bones appearing normal except for generalized decalcification. The lungs also show emphysema and an old tuberculous infection of the right upper lobe, which is probably healed. The left costophrenic angle is obliterated by a small amount of fluid or thickened pleura.

The heart is small, and the aorta shows marked tortuosity, with definite dilatation of its ascending and arch portions.

DR. DAVENPORT: The roentgenograms show only a large abscess. There is no demonstrable tumor mass or sign of bony metastasis. This evidence is equivocal, as neither is necessary to sustain a diagnosis of bronchial cancer.

Summing up the findings then, we have a sixty-five-year-old man complaining of cough, persistent chest pain and constantly streaked sputum, with a demonstrable abscess and a sputum negative for tubercle bacilli. My working diagnosis on these findings is bronchial cancer with secondary abscess.

What treatment are we justified in offering such a man? If we are correct, he is doomed to a progressive and painful course terminating in death. An exploratory operation is certainly justified. Suppose we are wrong, what weight should we give that possibility? The outlook for cure in an abscess of such size and duration is uniformly poor. Dr. Richard H. Sweet* has found no case of spontaneous cure in such abscesses with a duration greater than six months. Our patient is still faced with a slower, less painful, but progressive process, which untreated may eventually cause death.

Knowing the outlook with less bold measures in either case, I should accept the risks of exploratory operation. Further decisions must await the findings at the time of operation. Drainage would be palliative only. With an irreparably damaged lower lobe, its removal, whether for abscess or cancer, offers the only hope of permanent cure.

DR. EUGENE R. SULLIVAN: Dr. King, you saw this case. Would you care to comment?

DR. DONALD S. KING: I saw this patient in consultation, and I know what was found at operation, so that I can hardly approach the problem of diagnosis with an open mind. I do, however, wish to give hearty support to Dr. Davenport's insistence that bloody sputum over a long period almost always comes from carcinoma. This is particularly true if there is bloody mucus rather than blood mixed with pus. In retrospect the diagnosis in this case seems almost established by the persistent bloody expectoration, with obvious weight loss and chest pain.

When I first saw the patient I advised against bronchoscopy or operation and suggested a trial of chemotherapy. Former experience, however, had given us little hope that sulfadiazine would have a favorable effect on such a chronic abscess.

I wonder whether bronchoscopy would have given a diagnosis and whether it would have helped in the handling of the case. Dr. McGahey helped in the operation, and I should like to have his opinion whether the process was so located that it could have been seen through the bronchoscope.

DR. CLAUD E. MCGAHEY: I believe it was so located. However, I am against the routine use of bronchoscopy in persons of this age group.

DR. KING: I think that I advised against bronchoscopy for two reasons: first, because of the patient's general condition and, second, because of the lack of clinical or x-ray evidence of bronchial obstruction, either partial or complete. I do not, however, have a dread of bronchoscopy if prop-

*Sweet, R. H. Lung abscess: an analysis of the Massachusetts General Hospital cases from 1933 through 1937. *Surg., Gynec. & Obst.* 70:1011-1021, 1940.

erly performed, and I should like Dr Davenport's opinion concerning the risk in this case

DR DAVENPORT I should not favor bronchoscopy here. We have rarely found a cancer in the range of bronchoscopic biopsy where there has been no wheeze or x-ray evidence of obstruction. Secondly, as I see the situation, I am committed to an exploration with or without a preliminary biopsy, and the results of bronchoscopy would not change the plan of treatment. A factor in a borderline case is the slight but admitted risk of bronchoscopy in a man showing x-ray evidence of a dilated and probably eggshell brittle aorta. I should accept this risk if I felt bronchoscopy might give evidence that would dictate the plan of treatment.

CLINICAL DIAGNOSES

Abscess of lung
Bronchiogenic carcinoma?

DR DAVENPORT'S DIAGNOSES

Bronchiogenic carcinoma
Secondary abscess

ANATOMICAL DIAGNOSES

Epidermoid carcinoma (Grade II), bronchiogenic
Abscess of lung

PATHOLOGICAL DISCUSSION

DR SULLIVAN Dr McGahey, you participated in the operation. Will you tell us your findings?

DR MCGAHEY I had the opportunity to follow this case with Dr Churchill, who subsequently operated on the patient. Efforts to establish a definite diagnosis did not include bronchoscopy because we thought that the procedure was too risky in a man of this age with a dilated and rigid aorta.

We questioned the benefits to be gained from external drainage but concluded that if we could minimize the cough by such a procedure the patient might be made temporarily more comfortable. The operation was thus undertaken primarily with palliation in mind and secondarily to establish a diagnosis that, in the event of malignant disease, would justify x-ray therapy later.

The seventh intercostal space was exposed over the left paravertebral area. The intercostal muscles were found to be moderately edematous. Needle aspiration recovered a few cubic centimeters of moderately thick nonfoul pus from a point about 5 cm deep to the eighth rib. A segment of the eighth rib was resected, and the subjacent tissue was found to be firm and rubbery, and grated under the cut of the knife. A biopsy specimen was taken. The cavity was then opened through this tissue and found to contain about

40 cc of nonfoul pus. Tube drainage was established.

Convalescence was uneventful. The cough was considerably lessened, but when discharged the patient was still having moderate discomfort in the wound.

DR SULLIVAN Microscopic examination of the material removed at operation showed an epidermoid carcinoma of comparatively low grade malignancy. It is therefore evident that the abscess was secondary to the neoplasm, as Dr Davenport predicted.

DR KING Was lobectomy considered?

DR MCGAHEY The growth had extended through the pleura at the site of drainage. In any event this man would not have been a reasonable lobectomy risk.

CASE 29022

PRESENTATION OF CASE

A thirty-three year old housewife entered the hospital complaining of frequency, nocturia and incontinence of one year's duration.

The patient's husband had been injured in an automobile accident fourteen months previously, and since then she had been very nervous. One year before admission she developed urinary frequency and slight nocturia, and on several occasions during sleep she had total incontinence. Urinary incontinence was very frequent during any emotional disturbance. There was no dysuria, chills, fever or weight loss, but the patient had noted tremor, sweating and emotional instability. For the two weeks prior to entry she had had five or six bowel movements daily and also mild epigastric distress after meals. There were no menstrual abnormalities.

She had had thyroid enlargement for a number of years and had been treated until ten years before entry. She had had a mild "nervous diarrhea" for three months, five years previously. She had five children, all born at home, no perineal repair had been performed.

Physical examination revealed a well developed and well nourished woman with warm moist skin, moderate flushing and dermatographia. The eyes were normal. The thyroid gland was slightly enlarged. Examination of the heart and lungs was negative. The abdomen was flat and soft. In the right lower quadrant was a nontender movable mass measuring 4 by 1 cm. Pelvic examination showed a slight rectocele and cystocele and a little prolapse of the urethra. No incontinence was demonstrated. The cervix contained a few nabothian cysts. The fundus of the uterus was not enlarged and was in normal position.

Carcinoma can be fairly well excluded, chiefly on the basis of lack of mucosal involvement.

Lipomas and leiomyomas occur in this area in the wall of the cecum. They are both rare. I do

Acute appendicitis is so frequent that very atypical forms of it are as common as any of the rare lesions of this area. However, in the absence of any history of pain and tenderness, I cannot make

FIGURE 1. X-ray Films before (A) and after (B) Evacuation of a Barium Enema. The arrows point to the minimal swelling of the mucosa of the terminal ileum.

not ever hope to make a preoperative diagnosis of either.

Large lymph nodes about the ileocecal valve, as part of a lymphomatous process or tuberculosis, could give a palpable mass indenting the cecum. However, these diagnoses could be made only by inference from evidence of either disease elsewhere in the body.

Regional enteritis sometimes starts in this way and produces a similar mass. However, there are usually more gastrointestinal symptoms than are recorded, and some pain. Moreover, the mass is often tender, at least slightly. There are ordinarily some fever and weight loss. The x-ray films are interpreted as showing only a pressure defect on the cecum and spasm of the ileum without sign of ulceration. In the face of the foregoing evidence I cannot make a diagnosis of regional ileitis.

that diagnosis. Still I would not be greatly surprised if this were a subsiding acute appendicitis.

Mucocoele of the appendix should be considered. A true mucocoele of the appendix is rare. They are usually larger than this and likely to give more local symptoms. In some cases there exists an antecedent history of appendicitis. A certain number of cases are believed to follow a ruptured appendix, with subsequent resolution and formation of a cystic cavity containing mucus. Wangenstein* has produced mucocoeles in animals in this manner.

Finally, carcinoids are rare, but the appendix is by far the commonest site in the gastrointestinal tract for this tumor. They may be locally recurrent or metastasize to the regional lymph nodes. They give mild irritative or obstructive symptoms

*Wangensteen, O. H., and Dennis, C. Experimental proof of the obstructive origin of appendicitis in man. *Ann. Surg.* 101 629 647, 1939.

as they progress. They occur at practically any age but most commonly in the thirties.

Before concluding, there remains one more aspect to be explained. The patient is described as having emotional instability, tremor and sweating. I cannot readily explain these symptoms, and I do not know how definite they were. Perhaps she was just a nervous housewife. They could represent residual hyperthyroidism. There is mention of some kind of thyroid trouble ten years previously. But the essentially normal basal metabolic rate, the normal pulse and the lack of cardiac enlargement after all these years are against it.

One might conceive of a remote interrelation of the nervous symptoms, the hypertension and the right-lower-quadrant mass. Carcinoid tumors are argentaffinomas and developmentally related to adrenal medullary tumors, which have been described as causing paroxysmal hypertension. But carcinoids are nonfunctioning tumors, so far as I know.

In summary, I attribute the urinary symptoms to post-partum damage of the pelvic floor. The emotional symptomatology and tremor can be assigned to a psychic origin. In the absence of more gastrointestinal data and on the basis of a small nontender movable mass indenting the lower part of the cecum, I hazard the diagnosis of carcinoid of the appendix.

DR. EUGENE R. SULLIVAN: Dr. Bartlett, you saw this case. Will you add to the discussion?

DR. MARSHALL K. BARTLETT: As stated in the history and as emphasized by Dr. Sarris, this patient's presenting complaint was urinary incontinence. The story was much more definitely one of straight exertional incontinence than is given in the summary, and we were satisfied that it was explainable on the basis of the trauma of repeated childbirth.

The finding of a mass in the right lower quadrant was entirely incidental, but once it was found it was obvious that its nature must be investigated and explained before dealing with the chief complaint.

In evaluating this patient before operation, our line of reasoning followed much the same pattern as that outlined by Dr. Sarris. We excluded a tumor of pelvic origin on the basis of the physical examination, and ruled out an intrinsic lesion of the cecum or terminal ileum by virtue of the x-ray findings. Some process involving the appendix seemed the best explanation for the constant pressure defect of the cecum, and we believed that either a mucocele or a carcinoid would be found.

DR. SULLIVAN: Dr. McKittrick, will you tell us about the operative findings?

DR. MCKITTRICK. We operated on this patient thinking she had a tumor of the appendix, possibly a mucocele or a carcinoid. The barium enema had shown a pressure defect of the cecum (extrinsic), and the fluoroscopist was satisfied that the terminal ileum was normal. However, the terminal ileum proved to be the site of an early but well-established and typical regional enteritis. The bowel wall was uniformly thickened, slightly pale and less pliant than normal. The lacteals were prominent. Enlarged soft lymph nodes were scattered throughout the entire small-bowel mesentery. The process extended 25 or 30 cm. proximal to the ileocecal valve, gradually shading off to normal small intestine about 45 cm. from the cecum. The latter was a little thickened and injected. We were faced with the problem of what to do about this serious situation. The patient presented none of the usual requisites for surgery, namely, obstruction or fistulas. In fact she had been bothered by her disease only on two short occasions. Experience with early cases of regional ileitis has produced equivocal data regarding the benefits to be gained from early surgery. However, this seemed an ideal case to benefit from surgery if the adherents of early radical excision are correct. An end-to-side ileo-transverse colostomy was done as the first stage of a two-stage right colectomy. During the subsequent operation, all the grossly involved ileum and as much of the mesentery as could be obtained were removed. Still later, a urethroplasty was done to cure the urinary incontinence.

DR. GRANTLEY W. TAYLOR: What was done with the distal bowel?

DR. MCKITTRICK: The open end was turned in.

CLINICAL DIAGNOSES

Mucocele of appendix?

Carcinoid of appendix?

Urinary incontinence, due to urethrocele.

DR. SARRIS'S DIAGNOSES

Carcinoid of appendix.

Relaxed pelvic floor, with incontinence.

ANATOMICAL DIAGNOSES

Regional ileitis, acute, active.

Normal appendix.

PATHOLOGICAL DISCUSSION

DR. EUGENE R. SULLIVAN: The last 25 cm. of terminal ileum showed a thickened wall with an edematous mucosa. Just proximal to the ileocecal valve the edema was more marked and accom-

panied by a few shallow mucosal ulcerations. The largest of these measured 1.0 by 0.3 cm. The attached mesentery of the small bowel contained many soft lymph nodes. Microscopically these showed no resemblance to the picture seen in sarcoid. The appendix was completely normal.

DR. McKITTRICK: Would a small-bowel series have revealed a clue to the true diagnosis?

DR. LINGLEY: I doubt that further examination of the small bowel by a barium meal would have led to the correct diagnosis. On these films there is excellent retrograde filling of the terminal ileum, and I should say again, even in retrospect, that the mucosa appears normal.

DR. SARRIS: Do you now believe that the serrations represent ulcerations?

DR. LINGLEY: They undoubtedly do.

DR. ALFRED KRANES: I should like to ask Dr. McKittrick why he considered this to be an early case of regional ileitis. What about the history of diarrhea five years previously? We know very little concerning the natural history of this disease.

DR. McKITTRICK: I confess that I used the adjective "early" to signify not the duration of the disease but the degree to which the pathologic process had progressed. The disease may well have been present five years, but it had not yet appreciably narrowed the lumen of the bowel.

HALF A MILLION TYPEWRITERS

It is an interesting commentary on the magnitude of the enterprise in which we are currently engaged that the City of Magnificent Distances, wherein is lodged the very nerve center of our efforts, has issued an appeal for five hundred thousand used typewriters. It seems incredible that there should be so many key positions.

One of the inalienable rights of a democracy is that on going to war it should have two fronts—the aggressor nations, the professional fighters, avoid this until the last ditch, but we insist on having our real front and our paper front. The Battle of the Solomons has its quiet periods, but the Battle of the Bureaus never ceases.

There has been some sniping lately on the latter front, which seems to be one of bureaucracy

versus the business of the Nation,—and that business at the moment is war and war production,—and a few of the absurdities of how a bureau does its work have been pointed out. The story has been told, for instance, of the “tired businessman,” trying to consummate a contract with a departmental office in Washington, who was required to obtain fifty-one signatures for his papers. And a federal co-ordinator has been defined as one who brings organized chaos out of regimented confusion. Then, the *Reader's Digest* gives us the story of a subordinate in the War Department, enthusiastic and therefore probably young, who suggested the destruction of a large accumulation of tattered and obsolete records. The written proposal went up the line from one office to another until it, too, like a rolling snowball, had acquired a formidable bulk of its own. Approval after approval was attached to it until finally it reached the ultimate authority; permission was given to burn the papers—provided that copies were made of all those destroyed.

The *Journal of the American Medical Association* takes strong editorial notice in its November 7 issue of the report of Senator Pepper's Subcommittee on Manpower of the Senate Committee on Education and Labor. Apparently ignorant of the inventories of available medical personnel made by the American Medical Association in 1940 and by the Procurement and Assignment Service in 1941, the committee proposes the establishment of still another civilian authority to supervise and control the drafting and recruiting of physicians. So do republics stagger and fall under the burden of their own accumulated processes of government.

Typewriters, we know, are a necessary part of the equipment of our navy from dockyard to submarine; our military establishments need them from Ayer, Massachusetts, to Sydney, Australia; on our far-flung battle lines their keys, poked by the ponderous forefingers of countless staff sergeants, crackle above the staccato notes of the tommy guns; and that is where they should go. If they are wanted mainly in the Nation's capital,

however, and if, as has been suggested, the true purposes of democracy are being buried beneath a mass of protocols, then the need for half a million typewriters reveals, as Mr Churchill would say, the very belly of the monster

THE DOCTORS MAYO

A WAS a little man of English, Flemish and French Huguenot ancestry born in the neighborhood of Manchester, England, the son of a seaman, having pursued a medical education in Manchester, Glasgow and London without staying long enough to get a diploma, decided at the age of twenty five to try his fortunes in America. This was William Worrell Mayo. He was a pharmacist in Bellevue Hospital, New York, in 1845, he followed the westward trek to Buffalo, thence to Indiana where, in Lafayette, he opened a tailor shop, and then pursued medicine again and received a degree in 1850 from the Indiana Medical College at La Porte. "He was never satisfied with things as they were, but always wanted to go further," wrote his son later. Accordingly, with his Scottish American wife, he went on to St Louis, where he obtained a medical degree from the University of Missouri, and to St Paul, he explored the new settlements in the Lake Superior district, was attracted by the fertile valley of the Minnesota River, became pursuer on a river steam boat and publisher of a newspaper, manufactured patent medicines, and settled for a time and began the practice of medicine in Le Sueur, where, on June 29, 1861, was born a son, christened William James. He failed to get a commission in the Civil War, but was in the thick of the defense of the frontier settlements in the Sioux uprising and was foremost in the care of the wounded. Finally, in 1864, attracted by the boom town of the new wheat country, he moved to Rochester, where, on July 19, 1865, a second son, Charles Horace, was born.

Dr Mayo became the horse and buggy doctor of the district — active, enterprising and ambitious. He used a microscope, gathered a library, organ-

ized medical societies, went on study trips to New York and Philadelphia and returned to practice the new surgery. For the two sons, the life was that of country boys: school, chores, sport and, especially, helping their father with his work. "It never occurred to us that we could be anything but doctors." Will went to the newly founded medical school of the University of Michigan at Ann Arbor, where his career was not impressive six years later, in 1888, Charlie graduated from the Chicago Medical College (affiliated with Northwestern University), where he sat under Senn, Fenger, Andrews, Davis and Dudley — good teachers and, fortunately, converts to Listerism. Without the advantage of hospital internships the boys went back to Rochester to help their father. To young Dr Will is attributed the statement: "I expect to remain in Rochester and to become the greatest surgeon in the world."

The "old doctor," as he was then called, had become the most widely consulted surgeon of the region. He had operated on thirty six ovarian cysts, with a mortality of 25 per cent. He had not adopted Listerism.

Young Dr Will made trips to New York for postgraduate study, watched the work of Sands and Gerster, became convinced of the value of Listerism, and brought it back to Rochester. In 1883, a tornado swept the town, and the total lack of facilities for care of the wounded, who had to be placed in a dance hall, suggested to Mother Alfred of the Sisters of St Francis the need of a hospital, which was duly built (it is said against the advice of Dr Mayo). Thus was founded St Mary's Hospital, with the "old doctor" as consultant and the sons in active charge.

It is impossible to trace adequately the growth of the Mayo enterprise. At first, the brothers assisted each other without specialization, but gradually Dr Charlie took charge of diseases of the eye, ear, nose and throat, bones, joints, nervous system and thyroid gland, and Dr Will covered the abdomen, pelvis and genitourinary system. Sister Joseph succeeded Mother Alfred and, besides having general charge, acted for years as

Dr. Will's first assistant at operations. Dr. Stinchfield, a local practitioner, was associated in the medical field, and later Dr. Christopher Graham. The sick and injured of a wide and increasingly populous countryside, having no nearer consultants than the Twin Cities, flocked to Rochester. Associates were added to the staff whose names are almost as familiar as their chiefs': Plummer, Judd, Wilson, MacCarty—to mention but a few of the older group. Addition after addition was made to St. Mary's, laboratories were established, hotels erected and used in part as hospitals, specialties inaugurated, and new office facilities and ambulatory clinics provided. In 1912, a system of fellowships was devised through which young graduates—on moderate stipends—could observe, learn and provide services. In 1915, a million and a half dollars was appropriated from surplus earnings to create the Mayo Foundation for Medical Education and Research, as a graduate department of the University of Minnesota, and four years later all the assets of the Mayo Clinic were conveyed to a trust to provide for the perpetuation of the clinic. The last great physical expansion was the completion of the new clinic building in 1938 at a cost of three million dollars—a skyscraper of fifteen stories surmounted by a bell tower with a carillon. In that year, Dr. Will ceased operating, and a year and a half later, a retinal hemorrhage wrote finis to Dr. Charlie's surgical work.

There is no mystery in the success of the Doctors Mayo. "Stress the unusual opportunity that existed in the time, the place, the general setup, not to be duplicated now," said Dr. Will, in authorizing the work. Health, ability, ambition, industry and fair dealing were basic elements. The peculiar traits and capacities of the brothers were complementary. From the first, they were systematic in visiting medical centers and bringing back whatever was worth while, and in supporting organized medicine and attending society meetings, presenting papers and participating in the discussions. They were frequent visitors to the clinics of McBurney, Bull, Abbe and Weir in New York; Price in Philadelphia; Fenger, Ochs-

ner, Senn and Murphy in Chicago; Osler, Welch and Halsted in Baltimore; and Cheever, Warren, Cabot and Richardson in Boston. Constantly, they communicated to medical journals their experience, which was usually greater than that of others. They made full use of all ethically permissible methods of publicity, and were unfairly blamed accordingly. The financial return was large, but it is stated that 25 per cent of their patients paid nothing, 30 per cent paid the bare cost, and from 45 per cent came the professional fees, which in the end, in the form of endowments for research and education, were "turned back to the People from whom it came."

Miss Clapesattle, editor of the University of Minnesota Press, to whom the writing of the Mayo biographies* was entrusted, has produced a work—almost monumental in character—covering a far wider field than the biography of three physicians. Its pages represent prodigious bibliographic research, documented in a section at the end of the narrative text. Each phase of the career of the three doctors is pictured in a setting of the locale and contemporaneous events, affording a usually interesting and often very valuable historical background: the founding, in 1903, of the Society of Clinical Surgery—the model for all peripatetic clinical groups; the beginnings and course of specialization at the clinic, the additions to the staff, the growth of laboratory work, and the undesired publicity thrust on the brothers and the accusations of unethical conduct that beset them; and the part played by the clinic in World War I.

Among the million patients who passed through the Mayo Clinic, among the uncounted friends in and out of the profession, among students and historians of the medical scene, there will be thousands who will read every word of *The Doctors Mayo* with intense interest. For the average reader, both lay and medical, the book is too long, too detailed, too anecdotal, too full of trivialities. There are occasional lapses from the canons of good taste, occasional inaccuracies and interpre-

*Clapesattle, H. *The Doctors Mayo*. 822 pp. Minneapolis: University of Minnesota Press, 1941.

tations of dubious validity, and rare mistakes. But these criticisms are in themselves trivial, and one can only admire the work of Miss Clipesattle in her portrayal of these three beloved physicians.

MEDICAL EPONYM

SOUTHEY'S TUBES

These tubes are described by Reginald Southey (1835-1899) in the report of a case Chronic Parenchymatous Nephritis of Right Kidney. Left kidney small and atrophied—old scrofulous pyelitis, which was read before the Clinical Society of London on April 27, 1877 and which appears in the *Transactions of the Clinical Society* (10, 152-157, 1877). A portion of the article follows:

I determined to endeavour to relieve her dropsy by mechanical means and to this end employed an apparatus which is, I believe novel in England. I had a small trochar made with two well fitting canulas but little larger than the ordinary subcutaneous injection needles these canulas instead of terminating with a protecting rim and with a little bulbous extremity.

They are inserted into the subcutaneous cellular tissue with great facility and with no more pain than the ordinary needle prick produces. The canula inserted parallel to the surface is left stuck in the skin and a long fine capillary india-rubber tubing is now drawn over the protruding bulb and tied *in situ*. This tying in of the canula is not essential or even often necessary.

The long ends of the capillary tubes are now carried outside the bed and into a pan beneath it into which the serous dropsical fluid drip or drains away.

One drainage canula was inserted into each leg and through the two tubes about 2½ pints or in fact 71 ounces, of dropsical effusion drained away each 24 hours with considerable relief of course to the tension.

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON ARRANGEMENTS

Owing to the restrictions on gasoline and train travel and to the scarcity of hotel accommodations in Springfield, the Committee on Arrangements will recommend that the Council rescind its vote of May 25, 1942, whereby Springfield was designated as the place of the annual meeting in 1943. This committee will further recommend that the annual meeting in 1943 be held in Boston on May 25 and 26. Both recommendations have been endorsed by the Executive Committee.

GORDON M. MORRISON, *Chairman*

STATED MEETING OF THE COUNCIL

A stated meeting of the Council will be held in John Ware Hall, Boston Medical Library, 8 Fenway, on Wednesday, February 3, 1943, at 10 30 a m.

Business

- 1 Call to order at 10 30 a m
- 2 Presentation of record of meeting held October 7, 1942 as published in the *New England Journal of Medicine*, issue of November 12, 1942
- 3 Report of Auditing Committee and of Treasurer
- 4 Reports of standing and special committees
- 5 Appointment of Delegates
 - (a) To the House of Delegates American Medical Association, for two years from June 1, 1943
 - (b) To the annual meetings of the five New England state medical societies in 1943
 - (c) To the Annual Congress of the American Medical Association on Medical Education and Licensure at the Palmer House, Chicago February 12 and 16 1943
- 6 Such other business as may lawfully come before the meeting

MICHAEL A. TIGHE, M.D. *Secretary*

The two following reports are submitted for the advance information of members of the Council.

REPORT OF THE COMMITTEE ON FINANCE

The Committee on Finance, after some preliminary correspondence met on December 10, on which date the various committees are obliged by the by laws to have turned in their estimates for the coming year. There were present Drs. Charles F. Wilinsky, Peer P. Johnson, Ernest L. Hunt, Edward J. O'Brien and John Homans. The Treasurer, Dr. Butler, was prevented by illness from attending. His absence made much of our information concerning the expenditures for the past year uncertain.

The committee had been informed however by Dr. Butler that the income and expenses of the Society for the year 1942 were likely to balance fairly closely. In other words there was little likelihood of a favorable surplus such as had been secured in previous years. In 1942 the loss in dues owing to the entrance of members into the military services was beginning to be felt. But the Society should still have enjoyed an income from dues of something like \$55,000. To this about \$3,000 in income from invested funds should be added making roughly \$58,000 in all. Much of this is guesswork since the Treasurer's books are not made up until the first of the new year. Very likely if the income and outgo nearly balanced the income was considerably less, since the budget of \$50,800 could hardly have been overspent by any considerable amount. Owing to the establishment of the Blue Shield the Committee on Public Relations exceeded its budget by about \$1,000 and the Secretary was obliged to exceed his budget by over \$1,300 on account of the new by laws and other extras. However, the Committee on Arrangements made \$3,000, which more than balances these sums. The Committee on Publications,

ments and medications as prescribed and directed by a person licensed to practice medicine, and the application of such nursing practices and procedures as involve an understanding of cause and effect in order to safeguard the life and health of a patient and others.

In other words, she is a woman (or man) of good education who has been given three years of intensive training in the basic medical sciences and in the care of patients under the constant supervision of nurse educators, medical educators and interns. She is a woman of a certain maturity, responsibility and independence. These qualities make her desirable for Army service, where situations may arise that call for rigid discipline as well as judgment and initiative. She works best on acutely ill patients in hospitals and homes, and in executive and administrative posts in hospitals and public-health agencies, and as a staff nurse. Her shortcomings are those that might be anticipated because her experience is limited to work in large hospitals filled with surgical and critically ill medical cases; she is often unwilling or unable to do cooking and housekeeping (this fault is not confined to this class of nurse); she is unhappy in caring for patients with chronic disease and for well babies; and she shows signs of being a specialist.

Several estimates of the number of registered nurses in this country have been recently made. They vary considerably. No conclusion can be reached by adding up the number of graduates of nursing schools in the last twenty or thirty years for several reasons: some graduates (7 per cent or more) do not take or pass state registration examinations or National Red Cross standards; many get married (the marriage rate for all nurses under forty is 48.4 per cent); and a few abandon their careers for other types of work, although some return as their circumstances change or the demands for service increase. The most authoritative recent survey is the National Inventory of Registered Nurses in 1941, which was summarized in the *American Journal of Nursing* (42:769-773, 1942) by Pearl McIver. A questionnaire was sent to the 369,287 nurses listed in the 1940 census. Answers were received from 289,286, of whom 173,055 (60 per cent) were engaged in practice. If those who did not reply are rated as inactive, then only 45 per cent of the total number were active. However, of the 116,231 inactive nurses who returned their questionnaires, 25,252 (22 per cent) stated that they were available for duty in case of need. In other words, in January, 1941, there were 198,307 registered nurses active or available in the United States. Approximately 50,000 nurses have been graduated in the subsequent two years. A second inventory has just been authorized to bring the statistics up to date.

Of the employed nurses in the 1941 inventory, 81,708 (47 per cent) worked in institutions, 46,793 (27 per cent) were on private duty, 17,766 (10 per cent) were in public-health positions, 5512 (3 per cent) were in industrial plants, and the other 13 per cent held miscellaneous or undescribed jobs. Nurses who were unmarried and under forty years of age numbered 98,693. Estimating physical disabilities at 20 per cent, it was probable that at that time (January, 1941) there were 75,000 to 80,000 nurses available and acceptable for war duty. This number has been increased by the graduation of several classes since, and by the recent Army rulings that married nurses are acceptable if they are not with their husbands and if they are willing to go anywhere and that women up to forty-five years of age may be acceptable.

These statistics clearly show that there are enough registered nurses to meet the demands of our armed forces.

But they are not being met. Figures given out by Miss Marian G. Randall, chairman of the Inventory Committee of the governmental Subcommittee on Nursing, showed 30,000 nurses in the Red Cross First Reserve in April, 1942. The monthly quota of 3000 since that time has not been reached. How serious the deficit is cannot be estimated, for exact figures are withheld on grounds of military expediency. The various states, in April, 1942, had contributed from 13 to 60 per cent of their quotas; Massachusetts was credited with 1206, or 20.5 per cent of its quota.

The military authorities are disturbed by this inadequate response. The American Nurses' Association, in co-operation with the League of Nursing Education and the Red Cross Nursing Service, early last year set up a committee, known as the Nursing Council on Defense, in each state. Since Pearl Harbor, the title has been changed to Nursing Council for War Service. These committees have been very active in securing nurses for the Army and Navy and in aiding in the major readjustments that have been forced on civilian hospitals, industrial plants and public-health and civilian-defense agencies. However, they do not have enough power to be effective. A serious shortage of nurses is reported from various parts of the country. The average hospital has lost only three or four nurses; but many state and mental hospitals and some metropolitan hospitals have suffered severely. Moreover, population shifts resulting from the establishment of war-industry plants have not been met by changes in nursing ratios.

The problem has many sides and is being met by a number of solutions. An obvious first step is now under consideration — that of fashioning an agency with power to induce nurses who should join the armed forces to do so, and with power to allocate important nursing teachers, supervisors and administrators to their jobs so that essential teaching and hospital services will not be stripped. Another step that provides quick results is the recall of inactive nurses. As noted above, more than 25,000 trained women indicated last year their willingness to return to duty should the need arise, and they are doing so. More than 700 have come back in Massachusetts, and the Committee on Public Safety, in co-operation with nurses' organizations, is striving to get others. It is obvious that service means dislocation of family life and jobs to many of them. Some are serving at considerable personal sacrifice; others can give only part of their time. The same is true for those who are handicapped by physical or age infirmities. Hospitals gladly make allowances for such factors. For those who need to brush up on recent nursing procedures, refresher courses have been given with federal grants-in-aid. More than 500 have attended courses in this state in the past year. However these re-activated nurses can take care of only a small fraction of the present deficit. It is clear that more nurses must be trained, as many and as soon as possible.

There has been a marked increase in the number of pupil nurses in accredited nursing schools in the United States in the last few years. There were about 79,000 of them in 1929, an average of 70,000 yearly in the next decade, and then a rise to 82,000 in 1939, 85,000 in 1940, 87,588 in 1941, and 91,457 in January, 1942. Thus there has been an increase of 11 per cent since 1939. Admissions in 1942 have been approximately 49,000, or 18 per cent more than in 1941. But authorities in Washington had set 55,000 admissions as the goal for this year. It was not reached in spite of an intensive campaign of adver-

tising and interviews in schools and colleges Does this mean that only 50,000 young American women can be yearly induced to take up nursing? Some nurse educators are inclined to believe that this is a saturation point for the profession Or does it mean that many who might enroll do not yet realize the need for nurses? Or that they are more attracted to the WAACs and the WAVES and defense industries, which have more to offer financially and patriotically in immediately useful war work?

Answers to these questions will influence greatly the educational plans now under advisement Schools of nursing have been criticized for rejecting applicants on the ground that unduly rigid entrance standards are responsible for the shortage of pupils That this is not so is shown by the fact that about one third of the women who enter nursing schools leave before their three years are up, according to figures published in the pamphlet "Facts about Nursing" issued by the Nursing Information Bureau in 1941 It appears that the greater part of this considerable wastage represents changes in career (marriage, industry) Scholastic failures are relatively few More lenient admission policies would undoubtedly only increase the wastage With the continuance of this loss, it is estimated that 26,000 to 28,000 nurses will be graduated in each of the years 1942 through 1944 Surely the totals are not large enough to warrant optimism concerning their adequacy in meeting the Nation's needs for war and for the care of the civilian population

A few remarks on nursing schools may be pertinent at this point There are 1300 accredited nursing schools in the United States They are run by educators of ability, and they have drawn freely from the pedagogical wisdom of schools and colleges Their standards are subjected to frequent review by the National League of Nursing Education and the state boards of nurse registration Legal requirements for registration of graduates are quite uniform Good moral character is universally demanded Four years of high school is preliminary educational background required by forty-four states Training must be of three years duration in forty-three states, but fourteen (including Massachusetts) allow six to twelve months' credit for college work Age at registration must be at least twenty-one in forty-three states The structure of the courses and the requirements for practice are the outgrowth of many years of experience on the part of those who have worked constantly with nurses Therefore any suggestions concerning their alteration because of the war emergency should get the consent and co-operation of informed sources before they are put into effect

An increase in the number of training schools waits on proof that existing schools cannot take care of the applicants for admission and on proof that the proposed new schools can provide facilities for turning out graduates acceptable to the boards of registration The trend of the past decade has been toward fewer and better schools similar to the trend in medical schools a generation ago Schools have been asked to admit three classes annually as another way of accelerating production Naturally the decision to do so must rest with the individual school according to the best method it finds of handling its teaching housing its students and caring for its hospital patients

We have listened to much criticism of the registered nurse and her school We are told that she knows both too much and too little that she wants to be a specialist that she dislikes work outside hospitals, that she is unwilling

to do housework and cooking and so forth All of us have had disagreeable experiences with this sort of nurse Nurse educators freely admit her existence We have also heard it asserted that schools teach much that is unnecessary, beyond the pupil's grasp and in a too rigid and complex fashion Again, responsible nurse educators agree in part, and point to their frequent consultation with pedagogical experts and their constant revision of curriculums Recently in this state a review of the contents of the various courses was begun at the direction of the State Board of Nurse Registration and the Nurses Association and with the advice of physicians in the several specialties But does it follow that better nurses can be produced if they are not taught so much and in a shorter time?

It does not seem wise to lower the entrance requirements for pupil nurses, for a high school background is essential, and a college course desirable if they are to absorb the training that they are offered Furthermore the quality of a product depends not only on the quality of the material that is put into it but also on the time that is allowed for its growth Judgment medical in sight and discipline take time to ripen More can be expected of a nurse trained for three years than of one trained for one year Nurses are what they have become today not because they have banded together in an exclusive guild that relegates the interests of patients and physician to a position below their own They are what their employers the physicians, have helped them to be The medical profession has fostered their development as nurses theists, operating room assistants, administrators and research aides every year it adds to their tasks more tests and treatments that doctors only were accustomed to perform This tendency has increased as the shortage of physicians has grown and nursing schools must continue to supply the demand Military authorities show their approval by accepting only the three year trained nurse Nurse educators resist the demand for thoughtless mass production, pointing to the unfortunate situation that followed World War I when many hastily trained nurses were thrown on the market who, unable to meet the requirements of boards of registration practiced an inferior brand of nursing that reflected on the profession and themselves English representatives who have seen their country struggle with a mass of volunteer and partially trained workers in the last three years have urged us not to lower our standards for those who must supervise auxiliaries

It comes down to this — one type of nursing school can not produce all types of nurses Nurses for general and home duty can be trained in a year or so by schools for licensed attendants as discussed in the next section Nurses for special hospital and war service must continue to be trained by the schools of nursing No shortening of the duration of their course should be recommended since this would interfere seriously with the quality of the graduates The three year course cannot be condensed by the elimination of vacations as the medical school course has been for nurse pupils get only three weeks vacation each year We do not feel competent to pass judgment on the possible elimination of subjects or of hospital affiliations for the same purpose but we can see disastrous effects on hospitals that have come to rely on the services of pupil nurses in the care of their patients if those services are taken away from them The League of Nursing Education aware of the critical shortage of nurses and the factors discussed above has made certain suggestions in co-operation with the Office of Civilian Defense and

the Sub-Committee on Nursing in Washington. The following is quoted from the *American Journal of Nursing* (42:1182, 1942):

While emphasizing the importance of maintaining adequate preparation, the Board [of Directors] recognizes that civilian hospitals are becoming more and more dependent on student nurses to care for their patients and to be ready for civilian emergencies. In view of this situation, therefore, the Board recommends:

1. That schools offering the three-year curriculum plan to complete within thirty months all organized instruction and clinical experience in at least the four major services, medicine, surgery, obstetrics and pediatrics, leaving six months free for supervised practice wherever needed in the hospital. This arrangement would also make it possible, should a plan be worked out in co-operation with Army and Navy hospitals, for students who choose to go into military service, to have such an affiliation during this six months; or later if the need becomes more acute, students might be released to enter military service at the end of 30 months.

2. That, where state laws permit, an accelerated program be planned for students admitted with two to four years of approved college preparation which would make it possible for such students to graduate at the end of 24 to 28 months. The length of time should be determined on the basis of the previous educational preparation of the student and her level of achievement in the school.

3. That schools of nursing critically examine their curricula and eliminate duplication in instruction and non-essential activities, giving emphasis to those elements in the curriculum that are most vital in terms of present and probable future needs.

4. That every effort be made to extend the use of auxiliary personnel in so far as this can be done with safety to the patient.

5. That in view of the greatly enlarged numbers of student nurses and auxiliary personnel in hospitals, definite measures be taken to retain and stabilize teaching and supervisory staffs to provide for the adequate preparation of students and the proper supervision of auxiliary workers.

A few final comments on the efficient use of the present store of nurses remain. Private-duty nurses must be prepared to render any service necessary in homes. "Luxury nursing" is out for the duration of the war. Patients must accept the decision of the hospital administrator and the clinical staff whether they need special nurses, and for how long, regardless of their ability to pay. The sharing of a special nurse by several patients has been tried and the experiment has failed, owing to personal difficulties. Hospital authorities have been asked to "alter their personal policies in ways which will encourage graduate nurses to remain in institutional service." This is a cautious expression of the fact that hospitals must pay their nurses enough to meet the competition of industrial nursing and non-nursing war work. Furthermore, the Congress of the United States appropriated \$1,800,000 in 1941 and \$3,500,000 for 1942 and 1943 for nursing education, these funds to be used to assist nursing schools to expand their teaching facilities and as scholarships for young women needing financial aid in undertaking a professional course.

Licensed attendants. A licensed attendant is defined in the law (Chapter 620) enacted in Massachusetts in

January, 1942, as one whose purpose is "to care primarily for convalescent or chronically ill patients or those suffering from minor ailments, in hospital or home, under the supervision and direction of qualified physicians" and "to assist registered nurses in the care of acutely ill patients in hospital or home, under the supervision and direction of qualified physicians." This law attempts to regularize a miscellaneous group of nurse workers for the protection of the public. Some are graduate nurses who did not take or failed to pass registration examinations; others are graduates of unrecognized schools of nursing or graduates of good schools of practical or household nursing, or women self-taught or sketchily trained in nursing homes. All of them could be licensed to practice if they passed the state examination for licensed attendants by August, 1942; since that time, they must show that they have been graduated from attendant nurse schools approved by the state nursing authority. Since registration is so recent a development, there are no reliable figures concerning the number of these nurses in the United States that can be used as an estimate of the aid which they can give in the present emergency.

The foregoing definition shows that the licensed attendant is designed to supplement the services of the registered nurse and to render those that the registered nurse does not. She must know how to cook and how to manage a household; she must have the humility to be content with caring for patients with minor illnesses and for well babies; and she must have the patience and persistence to serve chronically ill or elderly patients for months or years. To fulfill these duties, she does not need to have as much preliminary education or as much training in school and hospital as the registered nurse. While her weekly wages are less than those of the three-year nurse, her annual income is often as great or greater. Practicing physicians know her value; in fact, they really prefer her services when they have problems such as those listed above. Leaders of the nursing profession also recognize her worth and have sought for many years to establish her on the sound educational and legal basis that has now been effected.

Reasons for the tardy recognition and utilization of the attendant nurse are many. An irritating but minor one is her competition with the private-duty nurse. It would seem that physicians could lessen this by a wise choice of the type of nurse they need for any particular case, and that nurses could do their part in fostering co-operation by granting the licensed attendant some degree of participation in the American Nurses' Association. Such a step would go far in promoting mutual understanding and respect and make less likely the development of a rival organization with contests concerning fields of interest. Large metropolitan hospitals have long refused to employ attendant nurses because they are not trained adequately to serve seriously ill patients and because pupil nurses can render all necessary services to the rest. Now, however, hospitals are so short of staff nurses that they have begun to use attendants on certain wards and in certain situations, and on the whole, the experiment seems to be working well. Emergency medical units and the hotel hospitals now organized by the Office of Civilian Defense include licensed attendants. Veterans' Administration hospitals should find many places for them. Public-health nurses are finding them useful in extending their services. It is likely that military authorities will be forced to call on them for work in their hospitals for wounded soldiers and sailors to relieve corps men. So it is obvious that a broad career is opening up for the licensed attendant.

Nevertheless, her chief usefulness, and her chief interest to us at this time, is in civilian community service, for in case of disaster or epidemic, the bulk of the medical work will be done in homes.

There are now in Massachusetts eight schools for attendant nurses—Beverly Hospital, Harley Hospital, Household Nursing Association, Holden District Hospital, North Adams Hospital, Tewksbury State Hospital, Waltham Training School, and Robert Breck Brigham Hospital. There are three types of setup for such schools. One is quartered in a chronic hospital (such as Tewksbury) with a practice house on the grounds for training in home cooking and management. Another is centered on the public school system (as in the Rochester, New York experiment). The third, which appears best, is that of the Household Nursing Association, which gives two months of preliminary training in its central group of buildings, affiliates with a number of small neighboring hospitals for twelve months of ward work, and then supervises work in actual homes for six months. The Massachusetts Approving Authority demands a minimum of twelve months training. All these establishments are relatively inexpensive and should be multiplied throughout the State.

Long before Pearl Harbor, the far-sighted management of the Household Nursing Association made efforts to increase their enrollment. Their capacity with seven classes a year was 168, and their average pupil census was 125. They found that they could double this number without extending the hospital affiliations. The hospitals were so eager to secure the services of the pupils that they offered to pay the \$60 tuition for all applicants who could not afford it. Yet their enrollment did not increase, in fact, there were, at the end of November 1942, only 5 applicants for the December class, which normally numbers 18. They redoubled their efforts, with the aid of the Committee on Public Safety, and by advertisements and articles in newspapers, the radio and schools, with scanty results. As an example, one newspaper story netted several hundred replies, out of which came forty interviews and finally two unattractive applicants. Commissioner Downey informs us that efforts were made, a year ago, to enlist attendant nurse pupils by talks by teachers and personnel advisers in various high schools throughout the State, but that the experiment was such a failure that it has not been continued. The Waltham Training School may be forced to close for lack of pupils, and the other schools are similarly affected. What are the reasons for this general lack of interest on the part of young (and middle-aged) women in attendant nursing? Are they not sensitive to calls for patriotic and community service? The most likely answer is that they can get better pay and more attractive work and hours in stores and manufacturing plants, which are calling even more loudly for them.

Certainly leaders have proposed that, in view of the country's urgent need for nurses, we should concentrate on the development of the licensed attendant in all hospitals qualified to teach. They assert that these women can give satisfactory service and that hospital nursing and military authorities should be forced to conform before it is too late. The proposals have been approved by some physicians and are the reason for this general report. The Committee on Medical Education finds them unsound on several counts. The most insurmountable obstacle right now is the failure, after considerable effort, to fill already established attendant nurse schools, as noted above. Perhaps this could be done by some form

of the draft to which women are not as yet subject. But we doubt the workability of any scheme that would force people to perform tasks in which they are not interested. It might be that a section of the WAACs and the WAVES could be allocated for nurse training and duty in special situations; it would be hard to apply them to civilian use. It is stated that more candidates could be obtained if they had the opportunity to train in large metropolitan hospitals. Attendant nurse educators do not believe this. Furthermore the quality of service that can be rendered by an attendant nurse is adequate only for chronic cases, the elderly, the well babies and children, and for simple household situations. We know that five-minded, eager women can be taught in a very short time to give excellent auxiliary aid and even to perform difficult nursing, medical and laboratory procedures. Such training requires a great deal of individual effort and supervision. The average pupil and the average class in any program of mass production respond to a much lesser degree, hence the necessity for the three-year program for turning out workers who can serve in acute medical and surgical cases and in military situations. Attendant nurse and registered nurse educators and hospital executives all agree that to use attendant nurses for cases beyond their ability is a sure way to invite disaster. Finally the establishment of two types of nursing schools in one institution is hazardous. The content and scope of the courses are necessarily different, so is the type of work on patients, and all this would lead inevitably to social and professional jealousies and friction no matter how good the behavior of all, and impose a heavy additional burden of teaching and supervision on staffs that are straining every nerve to turn out the essential graduate nurse.

For Cross volunteer aides. In 1941 the American Red Cross and the Office of Civilian Defense arranged a program for the training of volunteer nurses aides. As it now stands it gives women who are American citizens of good character and between the ages of eighteen and fifty who have had a high school education and who are physically fit and able to stand hard work one hundred hours of training. Half this time is spent in classrooms, and half in hospitals under the supervision of nurses. After completing the course, the aides buy their uniforms and promise to serve a minimum of one hundred and fifty hours each year for the duration. Hours are quite elastic and not necessarily in one continuous stretch. In time of crisis it is understood that the service may be longer and may be called for at distant points. It is women such as these (140,000 of them) that helped England immeasurably in these last three years. It was hoped that 100,000 of them might be trained in this country by the end of 1942. Actually this goal has by no means been reached (about 4000 exist in Massachusetts). Yet the results have been extremely gratifying from many points of view. About five hundred training chapters are functioning throughout the country, seventy-one hospitals are now teaching or available for teaching in Massachusetts. These volunteers are coming largely from an older group of women. They are wives and sisters of men in service, some are doctors' wives, schoolteachers and business women. They take their work seriously, glamour girls do not last. They have won the respect and admiration of nurses. Hospitals are eager to get them. They have done much for patients. They have become interpreters of medical, hospital and nursing needs to the community. They will be a real source of help in case of disaster or

difficulties arising from the loss of trained nurses to the armed forces. They are to be complimented and encouraged in every way.

Ward helpers. Ward helpers act as ward maids and run errands for patients and nurses. As the shortage of nurses has developed, they have been given minor duties in the care of patients. Essentially their jobs are similar to those of the Red Cross volunteer aides. They are more reliable for routine daily service because they are paid. It is foreseen that situations might arise calling for regular work on the part of the volunteers that they could not afford to give without recompense, since to do so would mean the loss of jobs or the disruption of family responsibilities. Therefore it is agreed that the volunteers may, in such circumstances, be paid, suffering thereby the loss of their uniforms and their amateur standing. Ward helpers usually are trained in the hospitals where they work. They can also be obtained from the Household Nursing Association, where they are given a one-month preparation course.

Ward helpers obviously are valuable to institutions but do not meet other community needs. To supplement the services of nurses and attendants in homes it is proposed that women able and willing to do household tasks freely or for hire, sign up with some central office, such as a nursing registry or a public-health agency. The proposal is certainly worth attention, although it is hard to guess what the response would be.

ROBERT T. MONROE, *Chairman*

COMMITTEE ON MATERNAL WELFARE

ANALYSIS OF CAUSES OF MATERNAL DEATH IN MASSACHUSETTS DURING 1941

ECTOPIC PREGNANCY

As has been customary in previous analyses, all cases of ectopic pregnancy are grouped under this specific heading, although in one sense they are surgical complications. There were 6 maternal deaths due to ectopic pregnancy during 1941, twice as many as occurred in 1940. One autopsy was performed.

The first case was that of a thirty-six-year-old primipara who began to stain when about two months pregnant and continued to do so for one month. She had had attacks of knifelike pain in the lower abdomen for the two weeks prior to hospital entry, and vaginal examination on admission showed that definite placental tissue was extruding from the os. A moderate amount of this tissue was obtained by curettage, and a firm mass was found in the anterior cul-de-sac, for which nothing was done. The following day the patient went into shock, and at laparotomy, the abdomen was full of blood, the bleeding arising from what was apparently a ruptured left tubal pregnancy. There was a hematosalpinx on the right. Bilateral salpingectomy was performed. Peritonitis developed and death resulted. Autopsy showed extensive hemorrhagic peritonitis. The ruptured tube did not reveal gross or microscopic evidence of ec-

topic pregnancy. This case was an unfortunate one. Intrauterine and extrauterine pregnancy existing at the same time are not uncommon; neither is it uncommon to have a ruptured tube due to ectopic pregnancy reported negative by the pathologist. Had this patient been operated on the day of the curettage, before rupture of the tube had taken place, in all probability the fatality would have been averted.

The second patient was a forty-three-year-old woman whose history is most inadequate so that her parity is in doubt. She was seen first when in a state of collapse and shock from abdominal hemorrhage; she was taken to the hospital by ambulance and died a few minutes after entry. The diagnosis of ectopic pregnancy with massive abdominal hemorrhage is probably the correct one; however, the medical examiner, who is said to perform no autopsies himself, refused autopsy in spite of the requests for one by the patient's physician and by the superintendent of the hospital where she died. One of the striking deficiencies of medicine in Massachusetts that has been brought out by the maternal mortality study is the attitude of some of the medical examiners toward performing autopsies on patients who die in childbirth.

The third patient was a twenty-seven-year-old primipara who was seen by her physician because of sudden severe pain in the right lower quadrant. Physical examination was negative. The pain increased during the next few hours, and the abdomen became distended; the patient went steadily downhill and died at home before the ambulance arrived. The diagnosis of ectopic pregnancy, as in the previous case, is the probable one; however, as neither operation nor autopsy was performed, it cannot be confirmed. In the absence of nausea and vomiting, and in view of symptomatology of so few hours' duration, hemorrhage was the most likely cause of death, and ectopic pregnancy the probable source of the hemorrhage.

The fourth patient, a thirty-eight-year-old multipara who had had one abortion at five months, was seized with sudden pain in the lower abdomen, accompanied by vaginal bleeding, when approximately eight weeks pregnant. After consultation, ruptured tubal pregnancy was diagnosed, and at operation the left tube was found to be ruptured and was removed. The patient was given one transfusion of 500 cc. of citrated blood, in spite of which she died about five hours after operation. Delayed operation was not a factor in this case, since the patient was operated on soon after the diagnosis had been made; it is possible that additional transfusions might have averted the catastrophe.

The fifth patient was a thirty seven year old mul-
tupara on whom operation for repair of a rectocele
and fixation of the uterus was performed. At
operation a mass on the right side was found,
which was said to have been a tubal pregnancy.
Following this operation the patient became anuric
and died. The description of the operation states
that the uterosacral ligaments were plicated, and
in all probability both ureters were involved in
this operation, thus causing the anuria. Although
this death is attributed to extruterine pregnancy,
which was an incidental finding at operation, the
true cause was bungling surgery.

The sixth and final case was that of a thirty nine
year-old primipara who was hospitalized for ob-
servation because of vaginal bleeding. Because the
red cell count fell very materially, operation was
decided on. Ectopic pregnancy was found, and
both tubes were removed because of extensive
adhesions. The patient died three days later,
probably because of bronchopneumonia. There is
little to be said about this patient, she was appar-
ently doing well from the surgical standpoint but
expired because of a respiratory infection.

The two patients who died without operation
show how serious the result of hemorrhage may
be and how important it is that operation be per-
formed whenever the diagnosis of ectopic preg-
nancy is suspected. This is the only way in which
such fatalities can be prevented.

DEATHS

PETERSON — JOHN A. PETERSON, M.D. of Hingham
died December 26. He was in his seventy third year.

Dr. Peterson attended Powers Institute and received his
degree from the University of Vermont College of Medi-
cine in 1896. For four years after his graduation he prac-
ticed in Guilford, Vermont. He then went to Hingham.
He was former medical examiner of the Fifth Plymouth
District and a former member of the Massachusetts Medi-
cal Society and the American Medical Association.

His widow and a daughter survive him.

STICKNEY — EDWIN P. STICKNEY, M.D., of Arlington
died January 8. He was in his eighty first year.

Dr. Stickney received his degree from Harvard Medical
School in 1892. He was a fellow of the Massachusetts
Medical Society and the American Medical Association. He
was also a member of the New England Pediatric Society
and the Arlington Doctors' Club.

Two daughters, a brother and three grandchildren sur-
vive him.

MISCELLANY

ELLA SACHS PLOTZ FOUNDATION

During the nineteenth year of the Ella Sachs Plotz
Foundation for the Advancement of Scientific Investiga-
tion forty four applications for grants were received by
the trustees, thirty six of which came from the United

States, the other eight coming from six different countries
in Europe, Asia and North and South America. The total
number of grants made during this year was twenty six,
one of these being a continued grant.

In the nineteen years of its existence the Foundation
has made four hundred and fifty five grants to scientists
throughout the world.

In their first statement regarding the purposes for
which the fund would be used, the trustees expressed
themselves as follows:

For the present researches will be favored that are
directed toward the solution of problems in medicine
and surgery or in branches of science bearing on
medicine and surgery.

As a rule preference will be given to researches on
a single problem or on closely allied problems. It is
hoped that investigators in this and in other countries
may be found whose work on similar or related prob-
lems may be assisted so that more rapid progress may
be made possible.

Grants may be used for the purchase of apparatus
and supplies that are needed for special investigations
and for the payment of unusual expenses incident to
such investigations including technical assistance but
not for providing apparatus or materials which are
ordinarily a part of laboratory equipment. Stipends
for the support of investigators will be granted only
under exceptional circumstances.

In the past few years the policy outlined in the second
paragraph has been neglected. During the present great
need for funds grants will be given in the sciences closely
related to medicine without reference to special fields. The
maximum size of grants will usually be less than \$500.

Applications for grants to be held during the year
1943-1944 must be in the hands of the Executive Com-
mittee before April 1943. There are no formal applica-
tion blanks but letters asking for aid must state definitely
the qualifications of the investigator, an accurate descrip-
tion of the research, the size of the grant requested and
the specific use of the money to be expended. In their
requests for aid applicants should state whether or not
they have approached other foundations for financial as-
sistance. It is highly desirable to include letters of rec-
ommendation from the directors of the departments in
which the work is to be done. Only applications comply-
ing with the above conditions will be considered.

Applications should be sent to Dr. Joseph C. Aub, Mas-
sachusetts General Hospital, Fruit Street, Boston.

CORRESPONDENCE

EXPECTORANTS

To the Editor: I have been interested in reading in
the September 3 issue of the *Journal* the article on virus
pneumonitis by Drs. Dingle and Finland. There is one
point brought out by these authors to which I wish to take
exception. On page 394 they say: "Expectorants may
be helpful when sputum is scant. If they refer to the
commonly used stimulating expectorants which act by
virtue of the fact that they are excreted in the bronchi, the
use of such drugs seems irrational. They are supposed to
increase secretion by acting as irritants to the mucous
membranes where they are excreted. To irritate further
an already inflamed mucous membrane does not seem
likely to add to the comfort of the patient."

I am strongly inclined to believe that expectorants so used tend to increase cough in the acute stages of respiratory infections, and I have seen a number of cases of persistent cough and subacute cases that were promptly relieved when the patient stopped taking the expectorant.

GEORGE C. SHATTUCK, M.D.

25 Shattuck Street
Boston

* * *

Dr. Shattuck's letter was forwarded to Dr. Finland, whose reply is as follows:

To the Editor: According to my understanding, it is the purpose of an expectorant to decrease the viscosity of sputum and make it easier to raise, thus indirectly relieving the marked irritation that results from the difficulty in dislodging thick tenacious sputum during cough. Further relief from the irritation may be sought through the administration of generous doses of codeine or of suitable doses of such drugs as Dilaudid, if necessary. There is evidence to indicate that the viscosity of the tracheo-bronchial exudate is decreased by the usual expectorants and by the inhalation of moist air or mixtures of oxygen and small concentrations of carbon dioxide or compound tincture of benzoin (Basch, F. P., et al. *Am. J. Dis. Child.* 62:981-990 and 1149-1171, 1941, and *J. A. M. A.* 117:675-678, 1941; Nelson, E. E. *Internat. M. Digest* 40:183-185, 1942).

Dr. Dingle and I were only too well aware of the frequent ineffectiveness of the usual measures. It must be borne in mind, however, that they are undertaken in the first place because the symptom is troublesome. Although Dr. Shattuck's experience may not be unique, the reverse is probably more frequently observed: that is, expectorants are withheld because relief from their use is not anticipated. The physician finally prescribes them in desperation, after which the patient begins to raise sputum more easily and with less irritation. Both these circumstances may, of course, be merely coincidences in the natural course of the disease. Two things are certain: severe and irritating cough is one of the most troublesome features of the prevalent primary atypical pneumonias, and the relief of this symptom is very difficult.

MAXWELL FINLAND, M.D.

Boston City Hospital
Boston

APPROVED LABORATORIES

To the Editor: In the October 8, 1942, issue of the *Journal*, a communication from this department was printed giving a list of the laboratories approved for performing premarital and prenatal serologic tests for syphilis.

Four laboratories have been added to this list, which brings the total to thirteen. The list is as follows:

State Wassermann Laboratory, Boston
Boston Dispensary, Boston
Boston Health Department, Boston
Leary Laboratory, Boston
Massachusetts General Hospital, Boston
Peter Bent Brigham Hospital, Boston
Health Department, Brockton
Truesdale Hospital, Fall River
Providence Hospital, Holyoke
St. Luke's Hospital, New Bedford
St. Luke's Hospital, Pittsfield
Mercy Hospital, Springfield
St. Vincent Hospital, Worcester.

Those sending such specimens to laboratories are reminded that no other laboratories in the State are approved for performing these tests.

PAUL J. JAKMAUH, M.D., *Commissioner*
Department of Public Health

State House
Boston

BOOK REVIEW

Manual of Standard Practice of Plastic and Maxillofacial Surgery. Prepared and edited by the Subcommittee on Plastic and Maxillofacial Surgery of the Committee on Surgery, Division of Medical Sciences, National Research Council, and representatives of the Medical Department, United States Army: Robert H. Ivy, M.D., chairman; John Staige Davis, M.D.; P. C. Lowery, M.D.; Joseph D. Eby, M.D.; Ferris Smith, M.D.; Brig. Gen. Leigh C. Fairbank, Medical Department U. S. A.; and Lt. Col. Roy A. Stout, D. C., U. S. A. With contributions of John Scudder, M.D., and Frederick P. Haugen, M.D. 8°, cloth, 432 pp., with 259 illustrations. Philadelphia: W. B. Saunders Company, 1942. \$5.00.

The purpose of publishing a series of manuals on military surgery, of which this is the first one, is to present in compact form essential up-to-date and reliable information regarding military surgery to medical officers who are, by necessity, called on to treat the wounded under adverse conditions, as specialization cannot be followed to the same degree in military service as in civilian life. The degree of success of such a manual is proportional to the fulfillment of the above purpose, and so far as this book is concerned, the reviewer believes that it has fulfilled this requirement to a great degree.

The book is divided into four sections: reconstructive surgery (250 pages); maxillary surgery (79 pages); maxillofacial prosthesis (34 pages); and anesthetic technics (22 pages).

The section on reconstructive surgery is the most ambitious and thorough chapter. The author covers almost the entire field of plastic surgery. One is particularly impressed with the careful selection of plastic procedures, and the rejection of many complicated and unavoidable operations. It is well for military surgeons to pay special attention to the "don't's" that the author courageously emphasizes throughout the text. The greater part of this section is based on civilian types of injury. Although these are very useful and will undoubtedly act as a guide for the treatment of gunshot wounds, one would wish that the author had utilized part of the vast material published on this subject during World War I.

The section on maxillary surgery lays special emphasis on the early treatment of fractures, and outlines many useful suggestions and aids for emergency and first-aid immobilization of fractures.

The least impressive part is the section on maxillofacial prosthesis. It gives very little that the military dental surgeon can utilize for the treatment of the wounded.

The fourth section comprises two short chapters on the application of local and general anesthesia.

The book is well edited and contains many excellent diagrams and illustrations. It will undoubtedly be a useful reference book for those who are assigned to treat injuries of the face and jaws, as well as general injuries.

NUMBER 3

DISSOLUTION OF PHOSPHATIC URINARY CALCULI BY THE RETROGRADE INTRODUCTION OF A CITRATE SOLUTION CONTAINING MAGNESIUM*

CAPTAIN HOWARD I. SURY, MC, A US * AND FULLER ALBRIGHT, MD †

BOSTON

IN a previous communication¹ from this clinic the possibility of using an isotonic citrate solution at a pH of 4.0 to dissolve urinary calculi was discussed and the successful treatment of one case of bladder stones by this method was reported. It soon became apparent that this solution was too irritating for routine clinical use, it is perhaps of historical interest that the patient who had been successfully treated for bladder stones had a so called "cord bladder" and hence was not disturbed by the irritation. Furthermore, if citrate solutions by irritation give rise to bleeding, this continues since the citrate prevents coagulation of blood. A study was therefore undertaken to find a solution that would be not only effective in dissolving calculi but less irritating.

The speed with which various solutions dissolve calcium phosphate calculi was quantitated by the speed with which they decalcified rabbits' teeth², the irritability of the solutions was studied by noting their effect on the mucosa of rabbits' bladders³. A large number of organic acids were tried; the effect of pH, tonicity, temperature, pK of the calcium salt of the acid and so forth were studied; some of the underlying laws were formulated⁴, and finally an isotonic solution of levulinic acid at a pH of 4.0 was selected. This solution was found to be less irritating, albeit considerably less effective, than the original citrate solution. The net result was an improvement, however, and several successful clinical experiences were obtained.

At this juncture it was discovered that the addition of magnesium ions markedly reduced the irritability of levulinic solutions⁵, the same was found to be true for citrate solutions and they were once more taken up for clinical use. The

present paper is concerned with a report of the dissolution of phosphatic stones in patients in whom a citrate solution containing magnesium ions (Solution G⁶) was employed.

CLINICAL MANAGEMENT OF CASES

Infection

In most cases during the dissolution the patients received moderate doses of sulfathiazole or a similar drug to prevent infection if it was not present, or to reduce it if already present.

Apparatus

The main object, of course, is to keep the solution in contact with the stone as much as possible. The actual apparatus used in each case depended on whether one was working through a simple nephrostomy tube, a two way nephrostomy tube, two nephrostomy tubes, a ureteral catheter and a nephrostomy tube, or one or more ureteral catheters. Technical aspects also varied depending on the degree of patency of the ureter and on how irritable the bladder and urethra were. Solution G is somewhat irritating, and some patients developed bladder symptoms if the solution was allowed to come out through the bladder, whereas others did not. Cases 3 and 5 illustrate how this difficulty was overcome.

When the stones lie in the kidney calyces it is desirable that a slight amount of intrapelvic pressure be obtained to make sure that the solution gets around all the stones. However, the operator should see to it that this pressure is not continuous lest a constant back pressure stir up a pyelonephritis. This means that the solution must in some way be introduced intermittently. Figure

*From the Medical Service and Urological Service, Massachusetts General Hospital and the Department of Medicine, Harvard Medical School.
This work was supported by a grant from the Mary G. and Pittman Fund.
†Assistant urologist, Massachusetts General Hospital (on leave of absence).
Associate professor in medicine, Harvard Medical School, physician, Massachusetts General Hospital.

The formula of Solution C is as follows:
Citric acid (monohydrated) 3.75 gm
Magnesium oxide (anhydrous) 6.25 gm
Sodium citrate (anhydrous) 4.37 gm
Water q. s. ad 100.0 cc

1 illustrates one possible apparatus to obtain these ends.

With rare exceptions it is better that the fluid should not go in and out of one tube, as in the Munro⁵ tidal-drainage apparatus devised for irrigating so-called "cord bladders." The objection to such an apparatus arises from the fact that the

FIGURE 1. Tidal-Drainage Apparatus to Produce Intermittent Intrapelvic Pressure through a Two-Way Nephrostomy Tube.

A—tube from reservoir of fluid leading to Murphy drip; B—tube leading to waste-fluid; C—level where siphoning begins; D—level of pelvis; E—two-way nephrostomy tube leading to kidney pelvis; F—upright glass tube open at upper end; G—curved glass tube acting as siphon; H—board to which apparatus is fixed.

As fluid enters the system from A, the pressure rises until the fluid reaches C, the height of the siphon; at that point, fluid siphons off until air coming into tube F breaks siphon; the whole process then starts over again. The distance, C to D, measures the extent of intrapelvic pressure before the fluid siphons off.

dead space in the tubes is so great in comparison with the cavity being irrigated that a large proportion of the fluid that comes out of the cavity goes back into it again. The efficacy of such a system depends on the ratio of the volume of the viscus being irrigated to the volume of the dead space (tidal fluid). The Munro apparatus is very satisfactory for bladders but not for kidney pelves. If one cannot have a two-way drainage, as for example, when one is working through a ureteral catheter, it is necessary to inject the solution man-

ually into the end of the catheter or to use the alternate apparatus, devised by our colleague, Dr. Lawrence Kinsell, and shown in Figure 2. With the latter the constant presence of an attendant is required; this attendant can, however, be the patient himself.

If one is dependent entirely on the ureter for the introduction of the fluid, it is preferable to use a soft-rubber catheter (Bardam No. 10) because of the danger of erosion of the ureter after prolonged intubation with a hard-woven catheter. This soft catheter can best be introduced with the help of a fiber stylet; once in position it can be left for weeks (Case 6) or months, if one is to judge by experience with ordinary skin ureterostomies. The problem of keeping the ureteral catheter in place is a somewhat difficult one because of the tendency of the peristalsis of the ureter to displace it. This trouble has been overcome by the apparatus shown in Figure 2.

Evaluation of Results

For following the progress of dissolution and for determining just where the stone is in relation to the pelvis of the kidney, and hence whether fluid can be made to come in contact with the stone, an air pyelogram is most helpful (Fig. 5A and B). Air is preferred to a radio-opaque substance because it does not obscure the stone.

DETERMINATION OF CHEMICAL COMPOSITION OF STONES

Before attempting to dissolve a stone with Solution G it is, of course, necessary to know that one is dealing with a phosphatic stone. By a "phosphatic stone" is meant one composed of calcium phosphate with or without calcium carbonate or magnesium ammonium phosphate or both. In this clinic, to the present date, no attempt has been made to separate out the various subgroups of phosphatic stones. The composition can be determined by chemical analysis if a stone has been removed in the past, by circumstantial evidence¹ or by the x-ray appearance of the stone. This last method of analysis is most useful and has already been discussed¹; it will be taken up in more detail in another publication.⁶

CLINICAL RESULTS

Solution G has been used on approximately 20 patients. In this report 7 cases are presented. These have been selected to bring out certain points.

CASE REPORTS

CASE 1. (Long history of recurring bilateral calcium phosphate stones; etiology of first stones probably hypercalcaemia from immobilization and resulting atrophy of disuse; ingestion of milk and of calcium gluconate were added factors; stones on right dissolved with Solution G through nephrostomy tube.)

In 1928, W L (No 70740), at the age of 18, fractured his left femur and humerus. Because of nonunion he was immobilized in bed for 6 months and given large amounts

milk and the calcium gluconate. The fallacy of this procedure lay in the fact that there was no point in giving a high calcium intake since nonunion of fractures is due

FIGURE 7. Apparatus If Dissolution Is to Be Carried Out through One Ureteral Catheter

A—ureteral catheter B—proximal end of Foley catheter C—tube through which balloon of Foley catheter is inflated D and E—sutures fixing ureteral catheter to Foley catheter F—distal end of Foley catheter G—balloon of Foley catheter H—ureteral orifice I—distal end of ureteral catheter J—stone K—tube leading to reservoir of fluid used in bladder irrigation L—forceps M—glass T tube N—forceps on tube leading to waste fluid bottle O—rubber tubing P—syringe through which Solution G is inserted Q—small-caliber tubing similar to ureteral catheter R—three way stopcock S—tube leading to burette T—rubber tubing U—clamp V—burette W—end of tube leading to Solution G X—tube leading to waste bottle

Since it is very irritating to void around a catheter it is necessary to have a bladder catheter as well as a ureteral catheter. A Foley catheter is used since it can be drawn tightly into the bladder neck and thus securely fixed. In this way a fixed object is furnished to which the ureteral catheter can be securely fixed. To irrigate the bladder one clamps the tube at N and opens the tube at L thus allowing fluid to go into the bladder. To empty the bladder one opens the tube at N and clamps the tube at L.

If the patient is to work the apparatus himself it is suggested that the apparatus at the left of the diagram be used instead of a syringe. The patient fills the burette to the desired level by opening the clamp U. To put fluid into the kidney tube the burette is connected through tubes S and T with the small tube Q by adjusting the three way stopcock R. To let fluid out of the kidney tube Q is connected with tube A by turning stopcock R. If a No. 10 Baidam tube is used for the ureteral catheter and for tube Q the dead space amounts to 3 cc. for 125 cm. of tubing.

of milk and calcium gluconate by mouth. Bilateral renal stones developed for which there was adequate reason. (Immobilization alone produces marked hypercalcaemia to this was added a very high calcium intake from the

to lack of formation of a callus, not to lack of calcification of a callus.) Left pyelolithotomy was performed but the stone is not analyzed. Nine years later the patient again entered the hospital with bilateral stones. A right

nephrolithotomy and a right nephrostomy were performed. When the present studies were started he had been wearing a nephrostomy tube for 4 years and some large stones

burning on urination. At the end of 10 days the stones were definitely smaller (Fig. 3B). Each week thereafter showed further improvement until the stones were entirely

FIGURE 3. Roentgenograms in Case 1 before (A), during (B and C) and after (D) Dissolution of Stones.

In B, note that the small stone above the catheter has entirely disappeared and that the large stones below the catheter are much smaller; in D, note that the small residual shadow indicated by the arrow lies outside of the kidney pelvis, since air in the lower calyx does not extend to the shadow.

had formed in the right kidney (Fig. 3A). The serum calcium and phosphorus values were normal; the urine showed *Proteus vulgaris* on culture, which was probably the cause of the recurrent stone.

Solution G was introduced through the nephrostomy tube and allowed to pass out through the ureter, bladder and urethra. The solution ran approximately 9 hours a day between 7 a.m. and 7 p.m. The patient used in the neighborhood of 3000 cc. daily and did not experience

dissolved (Fig. 3C and 3D). The entire procedure took approximately 3 months; thereafter the nephrostomy tube was removed. During the time of irrigation the patient received 0.5 gm. of sulfathiazole three times daily. He was followed in the Out Patient Department for 1 year. At the end of that time *P. vulgaris* infection was no longer present; the urine contained some colon bacilli but was acid; a pyelogram showed no recurrence, and the patient resumed his work as a radio engineer.

FIGURE 4 Roentgenograms in Case 2 before (A), during (B) and after (C) Attempted Dissolution

Note that the stones which dissolved did so completely and that those that did not dissolve remained as they were because of lack of contact with the solution

CASE 2. (A man with a long history of recurring bilateral calcium phosphate stones; many operations; etiology of original stones obscure, possibly kinked ureters; more recent etiology infection with urea-splitting organisms; dissolution with Solution G through bilateral two-way nephrostomy tubes of those stones in contact with kidney pelvis.)

J. S. (No. 308796), in 1925, at the age of 17, developed stones in the left kidney, for which a left nephrolithotomy

CASE 3. (Attempted dissolution with Solution G through a nephrostomy tube of a stone not found at operation; difficulty with bladder irritability, which was finally overcome.)

J. D. (No. 236588), a 41-year-old man, entered with two stones in the left kidney pelvis and congenital absence of the right kidney. The serum calcium and phosphorus values were normal; the blood nonprotein nitrogen was slightly elevated. A left pyelolithotomy was performed

FIGURE 5. Further Roentgenograms in Case 2 to Show the Advantage of an Air Pyelogram (B) over a Pyelogram with Opaque Substance (A).

In B, note that the air does not extend down to the stone in the left lower quadrant of the picture but merely goes as far as the arrow; in C, which shows the stones after attempted dissolution, note that this stone remains undissolved.

was performed. In 1937, bilateral stones were found; in 1938 a right nephrolithotomy and a right nephrostomy were performed, and in 1939 a left nephrolithotomy and a left nephrostomy. The patient was referred to the Massachusetts General Hospital by Dr. Leo E. Gibson of Syracuse, New York.

The serum calcium and phosphorus levels were normal; the urine was constantly alkaline and contained *Escherichia coli* and a nonhemolytic streptococcus; the analysis of a stone that had been removed previously showed it to be pure calcium phosphate. Large bilateral stones were present (Fig. 4A). As the ureters were practically non-patent, it was impossible to use them for draining out the solution; consequently the nephrostomy tubes were connected to a modified Munro tidal-drainage system. This was without effect because of the large amount of dead space (see above). Therefore the simple nephrostomy tubes were replaced with two-way nephrostomy tubes and Solution G was allowed to run into one side and out the other (Fig. 1). The patient ran approximately 1500 cc. of the solution through each tube daily. Figure 4B and C shows the dissolution of the stones that were in contact with the kidney pelvis. Figure 5A and B shows the advantage of an air pyelogram for demonstrating the relation of the stones to the kidney pelvis. Unfortunately complete contact with the stones could not be made (Fig. 5B), so that the patient was discharged with a few fragments still remaining and sent back to work with nephrostomy tubes left in place.

but only one stone was found; accordingly a nephrostomy tube was left in place. An analysis of the removed stone showed it to be calcium phosphate. Two weeks after the operation Solution G was introduced into the pelvis through a nephrostomy tube at the rate of 40 to 60 drops per minute, but caused marked irritability when it reached the bladder. The patient was then cystoscoped and a soft-rubber ureteral catheter was passed to the kidney pelvis; Solution G was then introduced into this catheter and allowed to come out the nephrostomy tube. The stone was readily dissolved (Fig. 6A, B and C).

CASE 4. (Recurrent stones due to hyperparathyroidism; removal of parathyroid tumor, leaving residual stone in right kidney; stone stationary in size for a long period of time; then rapid growth following infection with *P. vulgaris* (*B. proteus*); dissolution of calcium phosphate cortex, with no change in calcium oxalate center, an outcome that could have been foreseen by x-ray studies.)

J. B. (No. 117408), a woman, had a right nephrolithotomy in 1938 at the age of 25; the stone was found to contain a large amount of phosphate and a moderate amount of oxalate. The serum calcium was high (12.1 mg. per 100 cc.), the serum phosphorus was low (2.7 mg. per 100 cc.), and a diagnosis of hyperparathyroidism was made. A parathyroid tumor was removed by Dr. Oliver Cope. There remained a small stone in the right kidney at the time of the parathyroid operation; this continued constant in size for the next 3 years. In June, 1941, however,

the patient was cystoscoped in an outside hospital and developed an infection with *P. vulgaris*. Thereafter the stone grew rapidly.

Although the center of the stone in x-ray films looked suspiciously like that of an oxalate stone, it was decided to attempt dissolution through a ureteral catheter. A No. 5 whistle-top catheter was introduced into the right kidney

during her second pregnancy she developed pyelitis. One year before admission she received a left nephrectomy because of calculus pyonephrosis. Six months later she had right renal colic and passed a stone. None of the stones had been analyzed. Four weeks prior to admission she developed complete anuria of 48 hours duration and attempts at ureteral catheterization were unsuccessful.

FIGURE 6 Koenigscopograms in Case 3 before (A) during (B) and after (C) Dissolution

Note that the stone is in contact with the pelvis is shown in B as a pyelogram

pelvis and left in for 24 hours during 14 of which 5 cc. of Solution G was introduced every 5 minutes. This catheter did not work very well however and the patient complained of pain accordingly it was withdrawn and a No. 10 Gareau catheter was passed. Five cc. of Solution G was injected into this catheter every 5 minutes for approximately 14 hours a day for 3 days. The Gareau catheter was then withdrawn and a No. 10 soft rubber catheter was introduced. The irrigation was continued for 6 more days. Figure 7A shows the stone before irrigation and Figure 7B after approximately 10 days of irrigation. It will be noted that the cortex of the stone was entirely dissolved. By more careful x-ray technique it was then demonstrated that the residual stone was calcium oxalate (Fig. 7D).

This case illustrates the importance of careful x-ray technique in order to rule out oxalate stones had it been known, as it could have been that the center of the stone was definitely oxalate the procedure would have not been attempted. As a matter of fact, the patient's symptoms were very much improved as a result of the procedure, and it is barely possible that the size of the stone was sufficiently reduced so that it may eventually be passed.

CASE 5 (Left kidney removed for calculus pyonephrosis remaining kidney totally blocked by right renal stone requiring emergency nephrostomy stones completely dissolved with Solution G bladder irritability overcome by closed urethral drainage.)

C.W. (No. 339467), a 25 year-old woman was perfectly well until 1½ years prior to admission. At that time,

A right nephrostomy was performed. The patient recovered from the operation and came under our control 3 weeks postoperatively. The wound was well healed the nephrostomy tube was draining well and she was passing nothing from the bladder. The blood calcium and phosphorus were within normal limits. The urine was alkaline and contained large amounts of pus. Culture showed *Staphylococcus aureus* and a nonhemolytic streptococcus. An air pyelogram revealed a stone 2 cm. in diameter in the right ureteropelvic junction and several small stones in the lower calyx (Fig. 8A). These had the characteristic x-ray appearance of calcium phosphate stones. An attempt was made to ascertain the patency of the ureter at this time but it was quite difficult to get liquid or air into the kidney pelvis. As salt solution was dripped into the nephrostomy tube it leaked out around the tubing. The lower calyx and infundibulum were apparently partially blocked by stone and mucus. By means of the Murphy drip apparatus we were finally able to run in Solution G very slowly. It was as if an exit for the fluid had to be dissolved out first. However, the lower calyx stone dissolved and the large pelvic stone began to crumble (Fig. 8B), later the larger stone completely disappeared (Fig. 8C). The patient had considerable bladder irritability once the solution began going through to the bladder. This complication was managed very easily by placing her on closed urethral drainage. Once she began to tolerate about 2000 cc. of fluid per day, the stone dissolved in about 10 days. Figure 8C is an air pyelogram showing that all the stones were dissolved. Figure 8D is a Neoskiodan pyelogram showing that although there

was still moderate hydronephrosis, the ureteropelvic junction and ureter became patent. The right nephrostomy

were hypercalcemia (serum calcium, 12.8 mg. per 100 cc.) and hypophosphatemia (serum inorganic phosphorus,

FIGURE 7. Roentgenograms in Case 4.

A—air pyelogram before dissolution; note the granular center and the less dense cortex of stone. B—stone after ten days of dissolution; note that the cortex has disappeared and that the remainder of stone has a granular appearance suggesting that it is an oxalate stone. C—larger magnification of A. D—a second roentgenogram of stone at same stage as B, with better x-ray technic to bring out the oxalate structure.

tube was removed, and the patient began to pass clear urine.

CASE 6. (A 15-year history of kidney stones, including right nephrotomy; a diagnosis of hyperparathyroidism made, and a parathyroid adenoma removed; bilateral stag-horn stones and pyelonephritis persisted; dissolution of stone on left through ureteral catheter.)

E. R. (No. 135241), a 49-year-old, married woman, first developed urinary symptoms at the age of 30. Three years later the late Dr. Arthur Chute removed three "alkaline stones" from the right kidney pelvis. Eleven years later she was referred to the clinic by Dr. Harvard H. Crabtree because of bilateral staghorn-kidney stones. Since there

2.3 mg. per 100 cc.), a diagnosis of hyperparathyroidism was made. A parathyroid adenoma was removed by Dr. Oliver Cope in June, 1938. (This patient was one of the two in the series of 68 patients with proved hyperparathyroidism who did not have an abnormally high calcium excretion in the urine when first seen.) She had an infection in the urine with the urea-splitting organism, *Staph. albus*, and was unable to acidify her urine. The phenolsulfonephthalein excretion was excellent, but the urine concentration failed to rise above a specific gravity of 1.012.

After the removal of the parathyroid adenoma the serum calcium and phosphorus values returned to normal, but otherwise there was no change in the patient's condition.

To be sure, the urinary calcium excretion fell from a normal level (about 90 mg. in 24 hours) to a low level (about 35 mg. in 24 hours). During the next 5 years she was followed in the Out Patient Department. The staghorn stones remained constant in size; the kidney function remained relatively unaltered. Small calculi were passed from time to time; these presumably were new stones due to the persistently alkaline urine.

On April 21, 1942, an indwelling soft-rubber catheter was introduced into the right kidney pelvis and dissolution of the stone with Solution G was started. The apparatus employed is shown in Figure 2. Two nurses were ob-

possible of course to introduce more fluid at a time; the largest amount used was 30 cc. The results are shown in Figure 9.

CASE 7. (Bilateral calcium phosphate and carbonate stones; etiology probably excessive intake of soda and cheese, left nephrectomy and right nephrotomy performed previously; attempt to dissolve stone in right kidney through indwelling catheter; cause of failure shown by x-ray study.)

R. W. (No. 354198), a 47-year-old, married woman, was admitted because of right renal stone. A left nephrec-

FIGURE 8. Roentgenograms in Case 5.

tained, one for each of two 8-hour shifts; it was their duty to introduce Solution G by a syringe into the catheter every 4 to 10 minutes, to allow the solution to remain in the kidney 2 or 3 minutes, and finally to let it drain from the kidneys. As the stones dissolved away it was

tomy and right nephrotomy had been performed 1 year previously. The patient was for a long time in the habit of ingesting large amounts of soda and cheese. Stones removed at two previous operations contained large amounts of calcium phosphate and calcium carbonate.

FIGURE 9. Roentgenograms in Case 6.

A—before irrigation, B, C and D—eleven, twenty and forty days, respectively, after onset of irrigation. Note that dissolution proceeded most rapidly in the calices. This was an unexpected result since it was feared that calyx stones would be the last to disappear.

The last stone removed from the right kidney was noted in addition to having a peculiar coating the external surface of which was not determined but which was thought to be clotted blood since it gave a strongly positive guaiac test. The serum calcium and phosphorus levels were within normal limits. A ureteral catheter was introduced into the right kidney pelvis and irrigations were carried out as in Case 5. Re-examination 6 days later showed a decrease in the size of the stone. Failure was undoubtedly

solution was prevented from coming in contact with the stone by a thin coating of unidentified material, possibly old blood clot.

The choice of apparatus depends on the individual case and the ingenuity of the operator. Ideally the hydrodynamics should be such that the pressure in the kidney is great enough to get

FIGURE 10 Roentgenograms in Case 7

A—stone before attempted dissolution B—pyelogram with opaque substance after failure to dissolve the stone. Note that the stone is coated with some substance that prevents the opaque material from coming in contact with it.

due to the capsule of organic material surrounding the stone which prevented its solution (Fig 10-A and B).

SUMMARY AND CONCLUSIONS

Citrate solutions rendered less irritable by the addition of magnesium are practical for the dissolution of urinary calculi composed of calcium phosphite, calcium carbonate or magnesium ammonium phosphate.*

Six selected cases are reported in which such a solution was used successfully for the partial or complete dissolution of stones, in 2 cases the solution was introduced through ureteral catheters, in the remaining 4 through nephrostomy tubes.

One case is reported in which attempted dissolution of a large stone was without success because the

the solution around the stone, but sufficiently intermittent so that a pyelonephritis is not produced by a constant back pressure.

For determining whether a stone is in contact with the kidney pelvis and for following the course of dissolution, the advantages of an air pyelogram are stressed.

The importance of the roentgenogram in determining whether the stone is of the soluble variety is pointed out, a case is cited in which the centre of the stone was calcium oxalate and hence indissoluble, a finding that could have been determined by suitable x-ray technique.

*The solubility of Sodium Citrate is probably increased by the fact that a pH is lower than that of the urine reaches. It may be that a solution with a pH of 4.5 would be long run better. What we could do is to decrease the speed of solution and might only the likelihood of solubility.

The form of such a solution (Sodium Citrate) is as follows:
 Citric acid 32.35 gm
 Sodium carbonate (anhydrous) 8.84 gm
 Magnesium oxide 3.84 gm
 Water qs ad 100.0 cc

As judged by solubility tests of calcium citrate solution on M.W.I. to in two cases it was that sodium citrate solution.

EPIDEMIOLOGIC ASPECTS OF ANTHRAX IN MASSACHUSETTS*

IRVING R. TABERSHAW, M.D.,† AND GEORGE E. MORRIS, M.D.†

BOSTON

TIMES of war bring a host of new problems and an intensification of old ones in medicine as well as in many other fields. Anthrax, known since antiquity as an agricultural disease, presents in these days of stress an increased potential industrial hazard, for, in the anxiety to get leather, hides are obtained wherever available. Many are imported from countries where anthrax is still a common disease. In this connection it may be mentioned that in 1938 in Bulgaria, with a population of only 6,500,000, between 800 and 1000 human cases and 2716 animal cases of anthrax occurred.¹ At present, many hides in the United States come from India and China, countries where anthrax is prevalent.

With the wartime influx of potentially infected hides, the epidemiologic control of anthrax presents a greater problem than ever. Public-health supervision of importation and transportation is imperative. Smyth,² in a twenty-year survey in the United States (1919-1938), reported an incidence of 1683 cases. In Massachusetts, in the seven and a half years, from January, 1935 to July, 1942, 43 cases have been reported. That the incidence has not been greater is merely fortuitous, and it may rise rapidly in the near future. Anthrax spores are extremely difficult to kill; and to this day no commercially practicable method of destroying spores in hides has been discovered, since all known methods are complicated and expensive. Although this was the first disease entity to be proved by Koch's postulates,³ no significant advances in its control have been made in the last twenty years.

Man and all animals, especially the herbivora, are susceptible to infection with *Bacillus anthracis*.⁴ Normally the organism is indigenous only in certain areas, called "anthrax districts," and in such places animals are sporadically infected during some period of the year, usually in the summer. Isolated cases, however, may occur at any time. Anthrax being primarily a disease of animals, it frequently happens that agricultural workers become infected. It is also apparent that workers who deal with any by-product of an animal may contract the disease; included among such workers are those who deal with hides, wool, bristles, and hair. Longshoremen, truckmen and a group of miscellaneous workers, such as brushmakers, butchers, gluemakers and upholsterers, may also be

infected. In animals, anthrax is caused by ingestion and any medium that spreads the bacillus may cause an outbreak. In man the spore usually enters through a break in the skin, forming the so-called "malignant pustule." It may, however, be ingested and, in some cases, as in woolworkers, may be inhaled, giving rise to the pulmonary form of the disease.

In 1940, the United States Bureau of Animal Industry⁵ decided that the possibility of the spread of anthrax to domestic animals from imported fomites was relatively slight and, with certain specified exceptions, lifted its restrictions on the importing of hides. It is important to recognize that this bureau is interested primarily in the control of animal disease and not in the control of human disease. Theoretically, consular inspection at the point of origin of foreign hides is maintained. In normal times this inspection is subject to error, and under the stress of war it can at best be only perfunctory. Dry hides that are imported are subject only to a treatment (with bifluoride or silicofluoride) known to be effective against rinderpest and hoof-and-mouth disease. The effect of this treatment on anthrax spores is unknown and may be presumed to be nonefficacious, since infections have occurred from hides that have been treated in this manner.⁶

There have been 4 deaths and 39 recoveries in the 43 cases that occurred in Massachusetts from 1935 to 1942. The incidence by years is shown in Table 1. An average of 5.7 cases a year have

TABLE 1. *Anthrax Morbidity and Mortality.*

YEAR	NO. OF CASES	NO. OF DEATHS	MORTALITY %
1935	3	0	0
1936	9	1	11
1937	6	0	0
1938	5	1	20
1939	2	0	0
1940	9	0	0
1941	6	1	16
1942 (to July 1)	3	1	33
Totals	43	4	9.3

occurred. The lowest incidence was in 1939, with only 2 cases, which was followed by a sharp increase to 9 in 1940. In 1941 there was a decline to 6 cases, and in 1942 up to the present writing (July 1), 3 cases have been reported.

The occupations involved are shown in Table 2. Massachusetts has a large leather industry, and this is reflected in the fact that tannery workers

*From the Division of Occupational Hygiene, Massachusetts Department of Labor and Industries.

†Physician Division of Occupational Hygiene.

account for 32 cases comprising almost three quarters of the total. The majority of men infected worked either in beam houses or in storehouses

TABLE 2. *Incidence of Anthrax according to Occupation*

OCCUPATION	NO OF CASES	NO OF DEATHS	MORTALITY
			%
Tannery workers	32	1	3
Truckmen and longshoremen	4	2	50
Hair and bristle workers	3	1	33
Agricultural workers	2	0	0
Woolsorter	1	0	0
Miscellaneous (welder)	1	0	0

No authentic case could be traced to infection from finished leather. The next largest group, truckmen and longshoremen (4 cases), were all engaged in the transportation of imported hides. One more case could be traced to hides, as a welder was infected from his equipment, which had become contaminated by unfinished leather. Hence in all, a total of 37 out of 43 cases, or 87 per cent occurred in connection with hides. In not a single case could the infection be definitely traced to domestic skins. In 1 case it was thought to be due to domestic sheepskins, but the tannery concerned handled large amounts of imported hides, and the chance of cross infection was considerable. In an overwhelming majority of cases goatskins coming from India or China were the responsible agents. Four tanneries account for the major amount of imports, and in them occurred 27 cases or 63 per cent.

Three cases occurred among workers in hair and bristles, one of whom developed the only case of internal anthrax in this series. This man had both cutaneous and intestinal lesions and died. Certain by-products of animals, especially hair and bristles, are still subject to sterilization; hence, although outbreaks do occur, they are relatively rare. Two cases occurred in men engaged in domestic agricultural pursuits. One was a veterinarian who autopsied the carcasses of several cattle that had died of anthrax; the other was the owner of a milk farm where the animals became infected by eating anthrax-infected horsemeat. One case occurred in a woolsorter who scratched himself and developed cutaneous anthrax.

Although only 4 truckmen and longshoremen were infected with anthrax, 2 of them died. This high mortality, although not significant because of the small number of cases, is directly attributable to the lack of knowledge of the hazard of the disease on the part of the transportation companies and their employees. It was, therefore, not recog-

nized until late, with a consequent delay in therapy. Among tannery workers, where anthrax is suspected in any cutaneous infection, diagnosis and treatment are prompt, with a consequent decrease in morbidity and mortality. In the 32 cases that occurred in this group, there was only 1 fatality.⁷

SUMMARY AND CONCLUSIONS

It appears to be impossible to destroy anthrax at its source. Sporadic cases of native origin will always occur. It is extremely difficult to disinfect hides and skins. The anthrax spore undoubtedly survives the first two or three processes in tanning—that is, washing, fleshing and liming—but probably cannot survive the entire process. No significant improvement in the method of killing anthrax spores has been evolved in the last twenty years; and even if it were possible to disinfect hides and skins, it is doubtful whether this would be warranted, especially at the present time. Therefore the method of control must be chiefly one of education and sanitary precaution until the hides have passed through the tanning process. The more severe cases and the most frequent deaths have occurred in truckmen and longshoremen, who are not aware of the possibilities of this infection and who neglect to report for treatment early. The prompt diagnosis and treatment in tannery workers seem in large measure responsible for the lessened mortality and morbidity among them. Physicians treating any cutaneous infection in a tannery worker or truckman should bear in mind the possibility of anthrax and should culture material from the lesion. In order to keep this disease in check effectively, an educational program must be directed toward truckmen, tannery workers, longshoremen and all others who handle imported hides, from their arrival in this country to their conversion into finished leather.

MONTESQUIEU: A BIOLOGIST OF THE EIGHTEENTH CENTURY

CAMILLE DREYFUS, M.D.*

NEW YORK CITY

IN HIS profound study of the development of modern medicine, Shryock,¹ speaking of the physicians of the eighteenth century, points out that Voltaire, the great lay critic, held saner views on medicine than did most of his professional compatriots. This fact constitutes perhaps one of the most striking features of the beginning of this remarkable century. The men who were guided by reason only, the "philosophers," did not have to overcome the bookish prejudices that surrounded stagnant medicine like a Chinese wall. For although at this time medicine was greatly harmed by Molière's biting mockery, it continued nonetheless to be merely a study and an interpretation of classical texts—as one might say, *more theologico*.

Medicine progressed with slower steps than did the other sciences. Where, indeed, are the physicians of this period who can be ranked with Linné, Buffon, Volta and Galvani?

Along with Voltaire, Shryock should have been able to quote Charles Louis de Secondat, Baron de la Brède et de Montesquieu (1689-1755), who throughout his work never ceased taking a great interest in medicine and physicians. The author of *L'Esprit des lois*² and *Lettres persanes*³ merits a place in medical history. I am sorry to state that I could find no mention of him in classical treatises.

I shall aim to fill the gap concerning a man who is considered rightly as one of the most humane and most eminent writers of French literature and whom physicians can be proud to count as one of theirs.

How did this man treat the field of medicine?

The Academy of Bordeaux, of which Montesquieu had been a member since 1716, had chosen as the prize subject "The function of the renal glands or atrabiliary capsules" (we should say, "The physiology of the suprarenal glands"). On August 25, 1718, Montesquieu announced in a speech before this esteemed society that the prize of the Academy could not be awarded to any competitor. In a clear statement, which showed his deep knowledge, he gave the reasons for this decision. But his interest was attracted by an abstract that had been submitted.

Another [he said] who fortunately defined the difference between conglobated and conglomerated glands considered the atrabiliary capsules as a conglobated one. He believes that they are only a continuity of vessels in which the blood like in channels is subtilized. . . .

In these glands, and in every conglobated gland, there is no excretory duct, because there is no matter to separate liquids, but only to subtilize them. This system, not without some appearance of truth which is captivating at first, had attracted the attention of the society. But the author could not maintain his thesis.

And while the author of this luminous hypothesis still remains unknown, Montesquieu at least deserves credit for having transmitted it to our admiration. We know today how true this thesis was! But it was a long time before our knowledge was acquired. Anatomists like Gegenbaur† rejected even in 1903, about two centuries after the meeting of the Academy of Bordeaux, the idea of glands in which the excretory duct is supplied by blood vessels. Can we, therefore, upbraid Montesquieu for having doubts about this thesis, which seemed unlikely even to unquestionable masters of anatomy in our time? The members of the Academy assured themselves of the difficulties of the subject. They ordered experiments and dissections to be made so that they could "see with their own eyes," and thus they understood why the solution of the thesis had not been found.

"Chance will perhaps do some day," Montesquieu added, "what every effort could not do." And he closed his speech with these words which investigators can use as a motto:

Those who make their profession the seeking of truth are no less subject to the caprice of fortune than are others. What today costs so much needless toil can perhaps not withstand the first considerations of a happier author. Archimedes found while taking a delightful bath the solution of the famous problem which he had missed a thousand times while reflecting deeply. Truth seems sometimes to run before the seeker. Frequently there is no interval between desire, hope and enjoyment. Poets tell us that Pallas went out of Jupiter's head without pain, to make us conscious that the products of the spirit are not always tiresome.

The "Observations on Biology," which Montesquieu read on November 20, 1721, merits our admiration because it demonstrates the probity and the scientific spirit of the author. What a diversity of related facts! The pigmentation of insects was studied microscopically, the parasitism of mistletoe was examined carefully, the abdominal circulation

†Gegenbaur† writes: "We used to range thyroid and thymus along with some other glands, which have a 'mysterious' physiology, as 'blood glands.' Some authors consider them as glandular organs in which the excretory duct is replaced by blood vessels. The excretory duct, however, constitutes an essential part of a gland, which cannot be supplied by blood vessels. It is by no means evident how blood vessels physiologically can supply a part of an organ or how these organs secrete something that goes into the blood."

*Formerly, research fellow, Tufts College Medical School, aided by a grant from the Durkin Foundation for Medical Research.

of the frog was exposed with great precision. Finally, many problems of vegetal physiology, as well as studies on the foramen ovale and Botrillos duct, are noteworthy. The last chapter of these observations concerns experimental researches on the nutritional value of some vegetables.

One imagines [he wrote] that only wheat has food value for the human being and one considers that the other plants are merely of medical use. Physicians find them emollient, diuretic, desiccative or astringent. They treat all like manna, which nourished the Jews and which they use as a purgative. They give them an infinity of qualities which they do not have and nobody thinks of the nutritional virtue which they have. Wheat, barley, rye, like other plants, have years which are very favorable to them. There are years when the scarcity of corn does not constitute the unique misery which causes sorrow to people. Their bad quality is still more cruel. In these years calamitous for the poor and a thousand times more calamitous for the rich in a religious nation, we are able to supply the deficiency of corn. We have under our feet in every wood a thousand resources, against dearth and for that we should praise instead of curse Providence if we would know all his benefits. And therefore we intend to examine plants, herbs and an infinite number of things which apparently have no nutritional virtues. Animals which have some resemblance to human beings can well be used for this purpose. We have begun some of these experiments with great success. The shortness of time does not permit us to quote them here.

What a pity that this report did not come down to posterity! Montesquieu told us that his research work was the fruit of leisure hours in the country. For the author of *L'Esprit des lois* considered that leisure must be profitable to mankind. "Those who are living in a community," he wrote, "have to fulfill a duty, we have to account for every diversion."

Thus the lucid Montesquieu could only condemn and distrust the medicine of his time. He thought that the human spirit was stifled in the heap of theses of an obsolete and absurd "science." He held in abhorrence "this dreadful army of glossators and compilers who are as weak through the dullness of their advice as they are strong through their tremendous numbers." "And that is not all," he continued, "these foreign [Roman] laws have introduced formalities so excessive as to be a disgrace to human reason." And, again, "It would be very difficult to decide whether the pedantry has been more harmful in jurisprudence or in medicine, whether it has played more mischief under the cloak of a lawyer or the broad brim of a physician, and whether the one has ruined more people than the other has killed."

In a letter from a country physician to a physician of Paris, the mockery of Montesquieu reaches a peak.

There was once in our town a sick person who had no sleep for thirty five days. His physician ordered him opium but he could not make up his mind to take it, and when he had the cup in his hand he was less inclined than ever. At last he said to his physician, "Sir, give me only till tomorrow. I know a man, who although he does not practice medicine, has in his house an immense number of cures for insomnia. Let me send for him, and if I do not sleep tonight, I promise to return to you." The physician being dismissed, the sick man had his curtains closed, and said to his page, "Go to M. Anis and ask him to come to me." When M. Anis came, the patient said to him,

"My dear sir, I am dying. I can't sleep. Have you not in your shop the *Connaissance du globe* or some other book of devotion written by an R. P. I which you have not been able to sell, for long kept remedies are often the best?" "Sir," replied the bookseller, "I have the *Holy Court of Father Causin*, in six volumes at your service. I will send it to you and I hope you will be the better for it. If you would prefer the works of the Reverend Father Rodrigo a Spanish Jesuit you need not want them. But believe me you had better stick to Father Causin. I trust, with the help of God, that a single sentence of Father Causin's will do you more good than a whole page of the *Connaissance du globe*." With that M. Anis left and went to his shop to get the remedy. The *Holy Court* arrived and the dust having been shaken off of it the son of the sick man a schoolboy began to read it. He was the first to feel its effects. At the second page his utterance began to be almost inarticulate and already the whole company was growing drowsy. In a moment every body was snoring except the sick man, who after having stood it a good while was at last overcome too.

The physician arrived early next morning. "Well he said his mottoes been taken?" Nobody answered him. The sick man's wife daughter and little boy radiant with joy, showed him Father Causin. He asked what it was. They answered, "Long life to Father Causin, we must send him to be bound. Who would have said it who would have thought it? It is a miracle. Look sir look here is Father Causin. It is this book which has given my father sleep. And thereupon they explained the matter to him as it happened.

The physician was a skillful man versed in the mysteries of the Cabala and in the power of words and spirits. He was much struck and after deep thought resolved to change his practice entirely. Here is indeed a notable fact said he. It is a new experience and I must experiment further. And why should a spirit not be able to transmit to its work the same qualities which itself possesses? Do we not see it every day? At least it is well worth the trying. I am tired of the apothecaries their syrups the juleps and all their galeonic drugs destroy the health and the lives of their patients. Let us change the methods and try the power of the spirits. With this idea he drafted a new system of pharmacy, as you will see by the description which I am about to give you of the principal remedies which he employed.

A LIGHT PURGATIVE

Take three leaves of Aristotle's *Logic* in Greek, two leaves of a treatise on scholastic theology, the keener the better, as for example that of the subtle Scotus four of Paracelsus one of Avicenna six of Averroes

three of Porphyry; as many of Plotinus; and as many of Iamblichus. Infuse the whole for twenty-four hours, and take four doses a day.

This is only one example of a long list of prescriptions of the same kind. It would be too tedious to quote them. His favorite authors, I suppose, are not used as an ingredient of any decoction, even as an emollient one!

~ * *

"We have enough physicians. We now need medicine," he exclaimed once. He knew that there was no parallelism between medicine and the other sciences concerning progress.

Books of medicine [he wrote to express the same idea], those monuments of the frailty of nature and of the power of art, which, when they treat even of the slightest disorders, make us tremble by bringing the idea of death home to us; but which, when they discuss the power of remedies, make us feel as secure as if we were immortal.

Near these are the books of anatomy which do not so much contain descriptions of the parts of the human body as the barbarous names which have been given them — neither likely to cure the patient of his disease nor the physician of his ignorance.

People would perhaps blame Montesquieu for entertaining prejudices concerning medicine and physicians. Some may believe that his critical spirit prompted him to laugh at everybody and everything. But, satirizing with brilliant audacity the follies of his time, he could not avoid taunting our profession.

In a letter written May 5, 1753, to his good friend, Father de Guasco,* he expressed great admiration for Van Swieten, who was called by Maria Theresa from the Netherlands to Vienna to reorganize medical education. This famous physician, who was also chairman of the board of censors of Austria, authorized that Montesquieu's

book *L'Esprit des lois* could be sold in the Austrian Empire. Montesquieu held in devoted affection his physician Chevalier Louis de Jaucourt, who was a collaborator in the *Encyclopedia* for the section of physiology and pathology.

Montesquieu, who with his brilliant intelligence inquired into charges against the institutions and customs of his time, had to speak in his list of accusations of medicine and physicians. In the Academy he showed which way medicine had to take if the physicians would avoid irreverence and ridicule.

Antoine Portal, professor of anatomy of the Collège de France and the Jardin du Roy, gave this praise of Montesquieu: "We cannot say without admiration that, if Montesquieu had applied himself to anatomy, the progress of this science would have been as important as that of the ethical sciences under his guidance."

The mockery of *Persian Letters* is worthy of Molière's plays. Montesquieu's probity would not have permitted an unjust attack. He was a sincere moralist. "I never saw weeping without being moved with pity. I have committed many blunders during my life but never a malicious act."

He once wrote this sentence, which should win him immortality: "If I should know something useful to my fatherland but detrimental to Europe and mankind, I should consider it a crime." But Montesquieu knew that by remaining passionately a Frenchman he could be a good citizen of the earth.

MEDICAL PROGRESS

OBSTETRICS: MEDICAL ASPECTS

DUNCAN E. REID, M.D.*

BOSTON

AMONG the medical aspects of obstetrics, the toxemias of pregnancy continue to hold the center of interest because of their general influence on the occurrence of hypertension and albuminuria in women. Various attitudes regarding the relation of these conditions in pregnancy to the general problems of vascular and renal disease have led, in the past, to many differences of opinion. Contradictory results were often found, not only in clinical studies of these diseases but also in the physiologic studies made on patients. To promote a better understanding of the clinical syndrome known as the toxemias of pregnancy, a universal classification of diagnosis appeared most desirable. Through the American Committee on Maternal Welfare such a classification was presented in 1940¹; it has been accepted, and is now being used by all the large obstetric clinics of this country. This has been a landmark in the advance of the study of this disease for, although the classification may have certain weaknesses, it offers an opportunity to provide an accurate diagnosis in terms that are familiar to all. To emphasize the importance of this classification, it is given below.

GROUP A. Diseases not peculiar to pregnancy.

1. Hypertensive disease (hypertensive cardiovascular disease).
 - a. Benign (essential).
 - b. Malignant.
2. Renal disease.
 - a. Chronic vascular nephritis or nephrosclerosis.
 - b. Glomerulonephritis.
 - c. Nephrosis.
 - d. Other renal disease (such as pyelonephritis).

GROUP B. Disease dependent on, or peculiar to, pregnancy.

1. Pre-eclampsia.
 - a. Mild.
 - b. Severe.
2. Eclampsia.
 - a. Convulsive.
 - b. Nonconvulsive (that is, with coma and post-mortem findings typical of eclampsia).

It is evident from this classification that the obstetrician is aware of the role that vascular disease and renal disease play as a background for the toxemias of pregnancy (Group A). He also knows that the majority of patients with this syndrome develop, for the first time during pregnancy, varying degrees of albuminuria and hypertension (Group B). Finally, it is also realized that occasional cases may require a combined diagnosis from Group A and Group B, that is, pre-eclampsia superimposed on pre-existing vascular or renal disease.

With such a classification in universal use, and with the pooling of the experience from many clinics, it is possible to offer a solution of some of the problems that are bothersome during pregnancy, as well as to evaluate the renal and vascular sequelae that follow a toxemic pregnancy. Some of the more pertinent medical questions might be the following:

Which individuals with established vascular or renal disease should be allowed to continue their pregnancies?

If such patients are allowed to continue their pregnancies, what is the maternal and fetal risk involved?

What would be the effect of pregnancy on the course of the previously established vascular or renal disease of the mother?

What are the sequelae of the so-called "specific toxemia of pregnancy" on the vascular or renal system of previous normal persons?

Although many observations have been made to determine the ante-partum and post-partum status of the vascular and renal systems of patients in the different groups, no uniform answers to these questions have been given by the clinicians.

Albuminuria being a constant finding in the toxemias of pregnancy, attention was first focused on the kidney as the organ most profoundly affected by the course of this disease. However, it was soon found that marked changes could be observed in the liver, brain and other vital organs. Moreover, the degree of these changes was extremely variable. It has been emphasized that they are best explained by damage to the vascular system, particularly the small arterioles. Spasm of the smaller vessels oc-

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual, Vol. III, 1942* (Springfield, Illinois: Charles C Thomas Company, 1942. \$5.00).

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29031

PRESENTATION OF CASE

A thirty-nine-year-old man came to the hospital because of recurrent fractures of the right humerus.

Twelve years before entry the patient first broke his right humerus, while engaging in an arm-wrestling game. At this time the arm was immobilized in a sling for six weeks. Six years later, while hammering with a 5-pound mallet, the fracture recurred. After six weeks of immobilization in a sling, union was apparently firm. One and a half years before admission the humerus was again fractured when the patient attempted to raise himself through a trap door. The treatment was similar to and as successful as that previously employed. Two days before entry, following what seemed to be slight trauma, the fracture recurred. The patient believed that though the same bone was involved each time, the fractures did not occur at the same level.

The family and past histories were noncontributory. He had never fractured any other bone.

Physical examination disclosed a well-developed and well-nourished man in no obvious distress. The examination of the lungs, heart and abdomen was negative. There apparently were false motion and soft-tissue swelling at the junction of the middle and lower thirds of the shaft of the right humerus, with slight anterior displacement of the distal fragment. The bones did not seem massive, and the skull was not enlarged. There was some pigmentation on the back.

The blood pressure was 112 systolic, 66 diastolic. The temperature was 97.6°F., the pulse 60, and the respirations 20.

Examination of the urine revealed a specific gravity of 1.018 and a neutral reaction; the sediment contained only a great deal of amorphous material. The blood Hinton test was negative. The blood calcium was 11.6 mg., the phosphorus 4.48 mg. and the phosphatase 17.1 Bodansky units per 100 cc.

An x-ray film demonstrated gross abnormalities of the right humerus in the upper three fourths (Fig. 1). There were large irregular areas of rarefaction along both the cortical and medullary

portions, giving the bone a cystic appearance. There was expansion of the shaft in its middle third, whereas in the upper third the shaft was narrow and increased in density, with coarse tra-

FIGURE 1.

beculations. There was a pathologic fracture at the junction of the middle and lower thirds, with slight anterior displacement of the distal fragments. Several cyst-like areas were seen in the lower part of the bone and in the upper shaft of the radius. The uninvolved portions of the bone were not definitely decalcified.

On the third day after admission, an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. FULLER ALBRIGHT: I cannot remember ever getting one of these cases right. If I do not get this one right I will be surprised and chagrined.

I see very few problems here. "There was some pigmentation on the back." We should like to know what kind of pigmentation. No, we do not really want to know, because it is not that! By "that" I mean osteitis fibrosa disseminata, which is often accompanied by areas of café-au-lait pigmentation. But since pigmentation was mentioned, they might have told us what kind it was.

The phosphatase is high for an adult. Even for a fracture it is high.

This is really an x-ray problem, and all we have to do is look at the x-ray films and make a diagnosis.

DR. GEORGE W. HOLMES: All these films were taken on the same day. They show a cystic lesion that ends abruptly. There is normal bone in the lower half of the humerus, and pathologic bone above it. It is an extensive lesion, with marked increase in the trabeculation of the entire upper end of the bone. There may be slight periosteal proliferation. Do you attach any importance to the fact that it apparently involved the end of the bone?

DR. ALBRIGHT: No. It can do this in either osteitis fibrosa disseminata or in osteitis deformans (Paget's disease).

DR. HOLMES: In Paget's disease the lesion always goes to the end of the bone. I am not saying it is Paget's disease.

DR. ALBRIGHT: But I have seen at least one good case of Paget's disease that did not go to the end.

DR. HOLMES: That may have been the exception that proves the rule.

DR. JOSEPH AUB: Did you say this was Paget's disease, Dr. Albright?

DR. ALBRIGHT: No, but I am going to.

The pathologic process involves not only the humerus but also, according to the record, the radius on the same side. That makes us think of one disease in differential diagnosis, namely osteitis fibrosa disseminata. We do not have to think of any other. I should like to see x-ray films of the hand of the same side. If it were osteitis fibrosa disseminata, it is very likely that there would be cysts in the hands as well, since the cysts tend to run up and down one limb.

I do not believe there is any question about the diagnosis. Probably, I am away out on a limb, but I should not consider any other diagnosis than Paget's disease. The x-ray film is absolutely characteristic. There is a sharp line of demarcation between the abnormal and the normal bone. The phosphatase level fits in very well. I do not know of any lesion other than Paget's disease that would give so much elevation in phosphatase for such a small lesion. I presume he had no bone lesions elsewhere.

DR. TRACY B. MALLORY: None were discovered.

DR. ALBRIGHT: The question comes up. Why did he have Paget's disease? Can Paget's disease develop in a fracture? I have never known of a case where this has been proved to occur. One often gets the history of fracture and, later on, full-blown Paget's disease in the same region, but in such cases x-ray films have never been available in my experience to show that Paget's disease was here at the time of the fracture.

I do not believe we have to consider sarcoma. We always worry about it when the fractures of Paget's disease begin to occur. I see no evidence of it here. Furthermore, the phosphatase should have been higher. However, let me take another look at these films with the sarcoma idea in mind. Where was the fracture?

DR. HOLMES: I cannot see it in these films, which I agree with Dr. Albright are characteristic of Paget's disease.

DR. ALBRIGHT: That is all I have to say and it is probably too much.

DR. MALLORY: Are there any other expressions of opinion?

DR. AUB: I think one has to consider the possibility of localized bone cyst, with change in shape because of the two previous fractures. Is that possible?

DR. ALBRIGHT: The phosphatase is too high.

DR. AUB: Yes, but if he had a fracture, it might go up.

DR. ALBRIGHT: It will take a good microscopic section to tell which it is anyhow.

DR. MALLORY: What would you say about bone cyst, Dr. Holmes?

DR. HOLMES: One might consider it in view of the history of multiple fractures. There are certain things here to make one think of it. The explanation of the peculiar deformity I should attribute to fracture; it is very characteristic of Paget's disease. If it is not that, I do not know what it is.

DR. ALBRIGHT: The first fracture came too late in life for one due to bone cyst, which usually fractures earlier.

DR. MALLORY: The great problem in these peculiar bone conditions is to establish a diagnosis by any means, and the question may well be raised whether the x-ray or histologic diagnosis is more reliable.

CLINICAL DIAGNOSIS

Bone cyst, with pathologic fracture.

DR. ALBRIGHT'S DIAGNOSIS

Paget's disease of bone.

ANATOMICAL DIAGNOSIS

Fibrocystic disease of bone.

PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was operated on by Dr. Henry C. Marble, who opened into what he believed to be a characteristic bone cyst. He curetted out a considerable amount of soft, gritty material. This was seen by several pathologists, one of whom said it was Paget's disease, but later retracted this diagnosis; one said it was fibrous dys-

plasia of bone; one could make nothing out of it but callus and repair. The cyst was packed with bone chips, and the patient made a fair recovery, went back to work and was quite well for a six-year interval. He then had another pathologic fracture and came in again. More x-ray films were taken on this entry, which Dr. Holmes will now show.

DR. HOLMES: They are poor films, and I cannot make much out of them. They are all taken through plaster and are overexposed.

DR. MALLORY: But there is no doubt about the fracture at that time.

DR. HOLMES: No; it is nice to have one thing about which we are certain.

DR. MALLORY: On the second occasion the bone was explored, and again, a cyst was reported by the surgeon. Once more the gritty material was curetted out, and again, the cavity was packed with bone chips. On this occasion Dr. Castleman considered very strongly the possibility of sarcoma. I disagreed, as did Dr. Granville A. Bennett and Dr. Henry L. Jaffe, to whom we sent the sections. Dr. Bennett having seen these sections and having reviewed the first ones is now convinced that the diagnosis of Paget's disease was erroneous. He is inclined to think that it is a fibrocystic process, whatever that may be. Dr. Jaffe thinks the most probable diagnosis is bone cyst. No one is willing to support Paget's disease.

DR. WILLIAM B. BREED: What do you think it is?

DR. MALLORY: I would like to make it fibrous dysplasia.

DR. ALBRIGHT: Paget's disease is both fibrous and dysplastic. I will grant you that.

DR. MALLORY: Would one in a case of Paget's disease find gross bone cysts filled with fluid? The description that the surgeon has given us is rather inadequate. I confess the fragments that we received following the curettage give little idea of the gross pathology. We have some good sections for histologic examination, however, and they do not look like Paget's disease.

DR. ALBRIGHT: An x-ray man calls any circumscribed bone lesion without calcium a cyst. Pathologists have to have fluid to call it a cyst, whereas a surgeon calls any fibrous tissue a cyst.

DR. MALLORY: Our sections showed mostly fibrous tissue and spicules of osteoid, with multiple very small cysts scattered through the tissue.

DR. ALBRIGHT: I should have to see it under the microscope. Have x-ray films of the bones of the forearm been repeated?

DR. MALLORY: No. The diagnosis I have to make is fibrocystic disease of bone. It certainly does not look like Paget's disease.

DR. HOLMES: If you look at the case from another angle, it is apparent that everyone disagreed except the radiologists and Dr. Albright. I obtained different opinions from several pathologists, so I think the diagnosis is Paget's disease. The majority rules!

DR. MALLORY: This is a very satisfactory result for the clinicians because we cannot prove we are wrong.

DR. ALBRIGHT: I should still like to see a section in the radius.

* * *

DR. ALBRIGHT (subsequent note): It has occurred to me that the biopsies were all taken from the site of the fractures. I think this explains the typical mosaic structure of Paget's disease, which was not found. The mosaic structure, of course, is one distinguishing feature between Paget's disease on the one hand, and osteitis fibrosa localis (bone cyst) and osteitis fibrosa disseminata on the other. I also looked up this patient and had serum phosphatase determined on November 1942, two months after the fracture. It was 1.5 Bodansky units per 100 cc. I therefore think must attribute the high phosphatase to the underlying Paget's disease and not to the fracture.

CASE 29032

PRESENTATION OF CASE

A sixty-year-old widowed telephone operator admitted to the hospital because of convulsions and loss of consciousness of two hours' duration.

The patient was in good health until two three weeks before entry, when she developed persistent, vague nausea and epigastric cramps. During this time she lost about 10 pounds in weight. Four hours before entry, when she was aroused from sleep to eat supper and go to her usual night work, she complained of numbness of hands. It was noted that her head was deviated to the right and that she seemed preoccupied. An hour later, she suddenly fell off her chair and had a generalized convulsion, lasting about seven minutes, in the course of which she lost consciousness, frothed at the mouth, bit her tongue and was incontinent. She remained unconscious and had two more convulsions, which were similar but first although more severe. A physician gave an injection of "morphine," pried a speculum from the patient's mouth and referred her to the hospital.

The family history was negative. The patient was previously healthy because of a heart murmur, which was frequently accepted. About a month before she was thought to have

She had had an uneventful menopause a year before entry.

In the two hours following admission the patient was unconscious. Her jaws remained firmly clenched on a mouth gag, and her head was turned toward the right. The extremities were motionless, except during two convulsions, the first left sided and the second generalized. There was incontinence of urine. In the next hour the patient recovered consciousness sufficiently to answer questions. During this time the left arm and leg were completely flaccid, with positive Hoffmann and Babinski reflexes. Tendon reflexes were exaggerated in the left leg. The neck was somewhat resistant to flexion. There was left-sided facial weakness of the central type. In the next half hour or hour the patient became mentally clear except for slight disorientation, and was able to converse freely. The signs of left facial paralysis disappeared, and the patient was able to move the left arm and leg. There was a suggestion of grasp reflex in the left hand, but other abnormal reflexes were no longer present. The fundi were negative, and the external ocular movements and papillary reactions normal. The tongue was bruised and lacerated, and could be protruded in the midline. The neck was no longer stiff. The lung fields were clear. The heart was enlarged slightly to the left. The heart sounds were of good quality, with a systolic murmur audible all over the precordium. A cardiac consultant made a diagnosis of moderate aortic regurgitation. The abdomen was obese, with no palpable masses. The pelvis was essentially normal.

The blood pressure was 170 systolic, 80 diastolic. The temperature was 100.5°F., the pulse 115, and the respirations 22.

Examination of the blood showed a red-cell count of 4,570,000, and a white-cell count of 11,900 with 92 per cent polymorphonuclears. The urine showed a +++ test for albumin. The blood Hinton reaction was negative. The nonprotein nitrogen was 26 mg. per 100 cc. An electrocardiogram showed unusually high P and T waves, but seemed within normal limits.

A lumbar puncture during the middle period of semiconsciousness gave clear colorless fluid under an initial pressure of 250 mm., with normal dynamics; it contained 237 red cells per cubic millimeter and gave a + test with ammonium sulfate. The total protein was 246 mg. per 100 cc.; the gold-sol curve was 5555555554. The spinal-fluid Wassermann reaction was unsatisfactory in one examination and anticomplementary in another.

A roentgenogram of the skull showed marked bilateral thickening of the inner table of the frontal bone. There were no other unusual areas of cal-

cification. The posterior clinoid processes were calcified. The sella was not enlarged.

There was evidence of a left homonymous hemianopsia on the morning after admission, but two days later the visual fields were normal. The patient remained slightly dazed. The temperature remained about 100°F. On the fifth hospital day the patient developed a stiff neck and had a series of convulsions that could not be controlled by luminal or rectal ether. After this, she passed into progressively deepening coma, and died on the eighth hospital day without regaining consciousness. There was terminal rise in temperature to 105°F.

DIFFERENTIAL DIAGNOSIS

DR. HENRY R. VIETS: The past history does not disclose any definite disease. The heart murmur that she had many years previously and that caused her to be turned down by a life-insurance company, although later accepted, can only be put down as a possible indication of valvular disease. The history of so-called "stomach ulcers" is even more vague. We have a note, moreover, that she was in good health a few weeks before the onset of her illness, and we know that she was working nights as a telephone operator even though her age was sixty. These facts would lead me to believe that she must have been in more than average health.

She developed persistent although vague nausea and epigastric cramps two or three weeks before the sudden onset of her epileptic attack. She had also lost 10 pounds in weight. These symptoms are not particularly suggestive of intracranial disease although they may denote some interference with the vagus nerves. Her weight is not given, but she is described as obese. This fact leads us to minimize the loss of 10 pounds. In a patient of slight weight, such a loss would be of much more importance.

We now come to the actual onset of a rather remarkable train of symptoms. The first symptom in the present illness was numbness of the hands. This was followed by some mental confusion or at least something that is described as a preoccupied condition with a deviation of the head to the right. The numbness of the hands is not particularly suggestive from the diagnostic point of view; the turning of the head to the right might indicate a spasm of the left sternomastoid muscle, and the preoccupation some vague mental state. After an hour she suddenly developed a generalized convulsion of severe degree, for it exhibited all the signs of marked epilepsy including loss of consciousness, frothing at the mouth, biting of the tongue and incontinence, as well as a sudden fall

off a chair. This was followed, moreover, within an hour or two by two more similar but even more severe convulsions, a condition of status epilepticus indicating a severe degree of cerebral dysfunction. Even after the patient entered the hospital she was unconscious and her masseter muscles were in spasm, with her head turned to the right. The convulsions continued, and then for the first time it is noted that one of them was on the left side of the body, thus corresponding with the turning of the head to the right, which was one of the earliest symptoms. Within an hour she recovered consciousness enough to answer questions. The whole episode of status epilepticus lasted six hours punctuated by various seizures. These left her with a left hemiplegia of the usual flaccid type, thus indicating the severity of the lesion, and with the ordinary positive Hoffmann and Babinski reflexes. For the first time it was noted that the neck was rather stiff, suggesting the presence of some foreign substance in the cerebrospinal fluid, probably hemorrhage.

Slowly the patient recovered consciousness and the paralysis disappeared, leaving her with a grasp reflex for a time, a common temporary residual of hemiplegia. The examination could then be made more in detail, and it was found that the pupils reacted normally and that there was no paralysis of the extraocular muscles or signs of choked discs. The neck, too, was no longer stiff; but we are not informed when this was discovered, and it is therefore difficult to say whether the absence of stiffness was subsequent to the lumbar puncture. We know that fluid was withdrawn at some time, but there again the timing is vague for it only states the "middle period of semiconsciousness." We presume this was on the evening of her illness, but the tap may have been performed later. The pressure was moderately increased, and there were over 200 red cells—whether they were crenated is not disclosed in the record. The total protein was ten times normal, and the gold-sol curve markedly affected. In spite of the fact that the fluid was colorless, there is every indication that considerable blood had appeared in the subarachnoid space some time prior to the puncture. It is important to know exactly when the puncture took place, for its timing is as valuable as the findings disclosed by examination of the sample. The Wassermann reactions were unsatisfactory, presumably because of the blood in the fluid. The other laboratory reports are not particularly helpful. A large amount of albumin in the urine is often found in cases of hemorrhage in the nervous system, particularly those of the subarachnoid variety. So far as I know this has not been explained. The low non-

protein nitrogen tends to rule out any chronic kidney condition. General examination showed moderate enlargement of the heart, with slight signs of aortic regurgitation. The electrocardiogram, too, was within normal limits, and I cannot see that the roentgenogram was helpful. The left homonymous hemianopsia is part of the left hemiplegia, only sensory rather than motor, and I presume that at the height of the left-sided motor paralysis there probably was a left hemianesthesia. This would be impossible to test for in her condition of semicoma.

The patient did fairly well in the hospital for three or four days, although always somewhat mentally confused. The signs of hemiplegia and hemianopsia disappeared. On the fifth day she again developed a stiff neck, indicating a fresh outpouring of blood into the subarachnoid space. This was followed by another series of convulsions. Subsequently coma developed, and the patient died on the eighth hospital day without regaining consciousness. There was a terminal rise of temperature.

The sudden onset of severe epilepsy leading to cerebral attacks can only indicate a severe intracranial lesion. We have evidence, on account of the left hemiplegia, that at least the major portion of the lesion was on the right side of the brain. This was confirmed, moreover, by the later discovery of homonymous hemianopsia. Sudden epilepsy is most likely due to cerebral thrombosis, although it may be the result of cerebral hemorrhage, particularly if the hemorrhage is cortical or meningeal. The slow onset of this patient's condition in which she had symptoms at least an hour before the generalized convulsion, is strongly suggestive of thrombosis rather than of hemorrhage. Although theoretically we assume that thrombosis is more likely than hemorrhage, we have the definite fact that there was blood in the spinal fluid. The bleeding, moreover, was sufficient to cause some stiffness of the neck even on entry to the hospital. Subsequently the spinal fluid was indicative of a condition in which blood must have been present in large amounts at one time. This is the only way one can account for the increase in total protein to nearly ten times normal and the marked change in the gold-sol reaction. Although the red-cell count was only 237 at the time the tap was made, one has every justification in assuming that many more cells were in the fluid at some previous time, perhaps sufficient to make the fluid red in color. That the initial lesion was hemorrhagic in nature and subsequently bled again is indicated by the finding of stiffness of the neck and convulsions on the fifth hospital day. We thus may assume, I think, that a hemorrhagic lesion of some

sort was sufficient to cause the symptoms. Was this hemorrhage primarily in the subarachnoid space or within the cerebrum itself?

The transient nature of the hemiplegia and the homonymous hemianopsia suggest that whatever lesion in the right side of the brain caused these two findings, was far from permanent. This is, therefore, not suggestive of a thrombosis or of an intracerebral hemorrhage. A surface hemorrhage, however, would give such findings, for the pressure might rapidly be adjusted. Such a hemorrhage, moreover, would account for the cortical irritation giving rise to the status epilepticus. Although a thrombosis in general gives rise to epilepsy more frequent than does hemorrhage, that comparison is usually made with intracapsular hemorrhage and not with meningeal hemorrhage, which is in evidence here.

Embolism seems even more unlikely. In the first place, the history of heart disease is vague and even the examination disclosed only a moderate lesion that was not suggestive of activity. To be sure an aortic valvular lesion may lie dormant and subsequently a portion may come away and act as an embolus. This would not in all likelihood account for the hemorrhage into the subarachnoid space, and most cardiac emboli that enter the brain do so on the left side and give rise to right hemiplegia with its accompanying aphasia. Embolic lesions, moreover, are likely to be more fixed and not so transient in nature. I therefore believe that, although we may find evidence of cardiac disease, such as an aortic lesion, it is not likely that this lesion was the cause of death, even in a secondary manner through cerebral embolism.

Finally, we have to consider the likelihood of an aneurysm as the etiology of the subarachnoid hemorrhage. The onset of the illness is not quite so prompt as we find in most cases of bleeding aneurysm. We have, however, plenty of evidence that aneurysms may leak slowly and sometimes give symptoms for two or three weeks in advance of their rupture, such as might well have occurred in this case. The bleeding at the time of rupture may be sufficient to give a generalized convulsion. Apparently more blood appeared on the right side than on the left, and therefore the generalized convulsions were mixed with left-sided attacks. This condition quieted down; but after five days it was resumed in the hospital, and in three days death ensued. There is no indication where such an aneurysm arose. We must think of the usual position of these lesions in the circle of Willis, but in this case there is nothing to give us a lead concerning what part of the circle was affected.

We might be dealing, of course, with bleeding from some lesion other than aneurysm. Occasional-

ly we find symptomless gliomas that disclose themselves by bleeding. That is a possibility but a rare one. There are also vascular tumors such as hemangiomas, long quiescent, that suddenly announce themselves by bleeding into the subarachnoid space or into the brain. These lesions are rare, and although they are possibilities, in this case I do not believe we can make either diagnosis.

The diagnosis, therefore, is cerebral hemorrhage, possibly subarachnoid in type, more on the right side than the left. Aneurysm of a cerebral vessel is a strong possibility, with location not disclosed.

DR. EARLE M. CHAPMAN: Did you say that embolism in heart disease was statistically commoner on the left side of the brain than on the right?

DR. VIETS: Yes; I think that is right.

DR. JOST MICHELSEN: Do you think the combination of aortic regurgitation, the high protein in the cerebrospinal fluid and the gold-sol curve suggests a syphilitic lesion?

DR. VIETS: A gold-sol curve with so many S's in it always indicates that there has been blood in the spinal fluid. That is the only thing I know of that can give a gold-sol curve like this one. The high protein also means that there must have been some blood in the fluid. Whether that came from a vascular lesion other than aneurysm or hemangioma, I do not see how we can tell. There is no history up to the present illness that indicates that the patient had a hemangioma. She had no cerebral symptoms.

DR. MICHELSEN: If hemorrhage accounted for the high protein, would they not have seen a discoloration of the spinal fluid?

DR. VIETS: That is why I was interested in when the cerebral spinal fluid was examined.

DR. CHARLES S. KUBIK: It was done on the day after the patient was admitted.

DR. VIETS: That seems almost too soon for color to appear in the spinal fluid. A little yellow tinge I am quite sure is missed very frequently. If it is bright red anyone sees it.

DR. G. COLKET CANER: The facts that she lost 10 pounds in weight and had nausea and epigastric cramps, then woke up complaining of numbness of both hands give a vague impression of multiple lesions. Those things, together with the fact that she had a little blood and a high protein in her spinal fluid, indicating previous hemorrhage, make one think of the possibility of metastatic disease. There is not much evidence of it here, but there is a slight indication of multiple lesions.

DR. KUBIK: When I saw the patient I was impressed by the stiff neck and the red cells in the spinal fluid, thought of subarachnoid hemorrhage, wondered about the possibility of aneurysm but

ended up by saying that nothing I could think of fitted the picture very well. The important thing, it seemed to me, was to control the seizures, using ether anesthesia if necessary. Status epilepticus, regardless of the underlying condition, is likely to result in death, apparently from pulmonary congestion and edema. The ether should be given by inhalation.

Dr. Paul D. White saw the patient, and said:

A moderate amount of aortic regurgitation, dating back evidently fifteen years and therefore doubtless rheumatic in origin, is the only clear-cut finding on physical examination. This lesion is a good background for subacute bacterial endocarditis, of which, however, there is as yet no other evidence.

Red cells in the spinal fluid are often observed with cerebral complications of subacute bacterial endocarditis.

In view of what was found on post-mortem examination I am surprised that there were no white cells in the spinal fluid. I think that there must have been white cells.

Dr. VIETS: Of course that would change the picture a good deal.

CLINICAL DIAGNOSES

Cerebral hemorrhage.

Aortic regurgitation.

Bronchopneumonia.

DR. VIETS'S DIAGNOSIS

Cerebral hemorrhage, possibly subarachnoid
(? aneurysm of cerebral vessel).

ANATOMICAL DIAGNOSES

Neurosyphilis, meningovascular.

Syphilitic aortitis, with aneurysm.

Cardiac hypertrophy.

Pulmonary edema and congestion, slight.

Frontal hyperostosis.

Fibroid tumors of uterus.

PATHOLOGICAL DISCUSSION

Dr. TRACY B. MALLORY: Will you tell us about the cerebral findings at autopsy, Dr. Kubik?

Dr. KUBIK: There was no hemorrhage, no evidence of bleeding anywhere, either on the surface or within the substance of the brain, and no arterial occlusion or softening. There was one clue—a roughening of the ependyma of the floor of the fourth ventricle that was a little different from the usual so-called "granular ependymitis." This suggested neurosyphilis as a likely possibility, and the diagnosis was confirmed by microscopic sections.

There was an exudate of lymphocytes and plasma cells in the subarachnoid space over the brain stem and cerebral hemispheres. In the cerebral cortex and also in the cerebellum there

were scattered areas in which there was extensive perivascular infiltration with lymphocytes and plasma cells, nerve-cell degeneration and gliosis. No doubt there were many other areas like that. Some of these vessels were occluded. In other parts the cortex did not look very abnormal. There was an endarteritis of the medium-sized arteries in the subarachnoid space of the brain stem. I am not sure whether the diagnosis is general paresis or meningovascular syphilis but favor the former for the cortical pathology.

Dr. MALLORY: On examination of the cardiovascular system we found confirmatory evidence for the diagnosis of syphilis. The aortic valve showed a distinct separation of the cusps at the commissures, and the coronary arteries appeared to take their origin 2 or 3 mm. above the upper margin of the aortic cusps, thereby indicating that attachment of the cusp had gradually been lowered, as it so characteristically is in syphilitic involvement of the aortic valve. The ascending aorta was moderately dilated and showed a great deal of wrinkling. On microscopic examination there were focal destruction of the media and perivascular infiltration of lymphocytes in the adventitia and also in the vascularized media. I think that both the cerebral and vascular findings are characteristic enough to permit us to make a positive diagnosis even without serologic support. There was a slight pulmonary congestion and edema, secondary, I believe, to the status epilepticus. A coincidental lesion was hyperostosis of the frontal bones; I do not believe it played any part in the symptomatology.

Dr. CHAPMAN: Did you do a Hinton test on the blood obtained at autopsy?

Dr. MALLORY: No; such tests are usually not very satisfactory, since they are likely to give anti-complementary reactions.

Dr. VIETS: Do you want to comment on status epilepticus as the terminal event in a general paretic?

Dr. KUBIK: I think that a patient may die of status epilepticus quite apart from the underlying disease, which may be neurosyphilis, brain tumor or something else. Every effort should be made to stop the convulsive seizures and to do so as quickly as possible. The usual anticonvulsive drugs often have little or no effect on the convulsions, and when given in large doses, may do considerable harm. Ether anesthesia, in my experience, has been very effective, and I believe that it is also less harmful. It acts quickly and surely and is rapidly eliminated.

I should suppose that in the present case the patient died as a result of status epilepticus, with pulmonary congestion and edema as the chief cause of death.

PRESIDENT-EMERITUS LOWELL AND MEDICAL EDUCATION

THE late A. Lawrence Lowell, president-emeritus of Harvard University, always took a great interest in the Harvard Medical School. In June, 1939, he made some informal remarks on medical education to the Class of 1914 on its twenty-fifth anniversary. These remarks were subsequently published in the March 21, 1940, issue of the *Journal* and were commented on editorially in the same issue. This article reflects his considered opinion regarding the education of physicians.

Mr. Lowell always maintained that it was unwise to argue with an expert on the expert's own ground. Consequently, his contributions on medical education were by way of suggestions rather

than by declared policies. Mr. Eliot used the phrase, "prodigious advances in medical science," whereas Mr. Lowell referred to the "vast improvement in medical education." Perhaps Mr. Lowell's most concrete suggestion was the introduction of general examinations at the Harvard Medical School in 1914. These were largely based on the type of examination then employed at Harvard College.

Mr. Lowell was always distressed by the length of medical education. He once referred whimsically to the possibility that a man would be forced to retire on account of age just before he completed his training. He had the feeling that there were needless attempts to cover too much ground and that, of necessity, much of the material was forgotten by the student before he had any opportunity to put it to use. He claimed that there was a tendency to add the new to the old without sufficient effort to eliminate some things no longer needed, and believed that it should be possible to solidify and simplify the curriculum, in which he included the time spent in hospitals.

He was always very fond of the following anecdote. His brother once complained bitterly to his father, "Doctors really know very little." His father replied, "Yes, that is true, but the doctors know a little more than we do and so we find them valuable." Mr. Lowell would then go on to say that he had seen the situation entirely changed and that such a remark would not be appropriate today. He added, however, that the change, unfortunately, seemed to have been made at the cost of the withdrawal, as compared with former times, of the medical profession from civic affairs, to which they could contribute so much.

THE PERIOD OF RESISTANCE

MANY children—indeed it would be safe to say nearly all children—some time in their early, preschool years of life, enter a period of stubbornness, contrariness and spitefulness that, if improperly handled, may miscolor the rest of the stages of their lives and set a pattern for their maturer

years. By no means all children constitute serious problems at this period, but it is fair to say that any child worth the raising constitutes somewhat of a problem.

This period has for years been called the "neglected age" of childhood, the cause of the neglect lying quite reasonably in the attitude of the child toward interference with his independent desires; Benjamin,^{*} whose studies at Johns Hopkins University represent the most recent contribution to the problem, calls it the "period of resistance."

Underlying the spite and negativism that make up the chief characteristics of this period, with their varying expressions of misbehavior from thumb-sucking to bed-wetting, from temper tantrums to encopresis and head-rocking, is always a basis of anxiety or inner insecurity—the result of an unsuccessful transition from infancy to early childhood. All human personality difficulties stem from a combination of hereditary and environmental factors, as the architecture of any building must be determined by the type of building materials available, as well as the skill of the architect. With due allowance for the material utilized, these poor results are obtained from a training that does not give enough independence, or destroys self-confidence by punishment and frustration.

Benjamin's plea is for a family structure that recognizes the rights of all its members from the beginning. He writes:

Real democracy begins at the beginning, when neither parental nor infantile despotism should be allowed to govern the social unit which is the home. Disturbing rebellion, which is still so frequent in children . . . has no opportunity to flourish in an atmosphere of good sportsmanship, reasonable compromise, reciprocity and mutuality.

Unwholesome remonstrance can be prevented. Such an attitude is over and above the safest guarantee for the rearing of self-dependent, conforming, considerate, truly free and democratic Americans.

Undoubtedly, a fuller appreciation of this precarious period in early childhood by both physicians and parents will do much to prevent many of the difficulties that arise in later life.

MEDICAL EPONYM

SPRENGEL'S DEFORMITY

Otto Sprengel (1852-1915), chief surgeon at the Children's Hospital of Dresden, described "Die angeborene Verschiebung des Schulterblattes nach oben [Congenital Upward Displacement of the Shoulder Blade]" in the *Archiv für klinische Chirurgie* (42:545-549, 1891). A portion of the translation follows:

During the past year I have had the opportunity, four times in all, to observe a deformity of the shoulder blade in children of different ages, which, in the absence of any effective extrauterine causes, must be considered congenital. . . . This may be briefly characterized as follows: One shoulder blade (the left) lies about 2 or 3 centimeters higher than the other, without any other demonstrable anomaly of the back or thorax. . . . The fact that in the observed cases it was always the left shoulder blade which showed this anomalous position must be considered a matter of chance.

SOCIETY HEADQUARTERS

Owing to the decreased supply of fuel oil, the Boston Medical Library will continue to be closed on Saturday and will be open from Monday through Friday from nine in the morning to three in the afternoon, until further notice. The headquarters of the Society and the offices of the *Journal* will be closed to conform with this schedule. In an emergency, the officers of the Society and the managing editor and associate editors of the *Journal* can be located through their other offices or homes.

SECRETARY'S OFFICE

The following letter is published for the information of members of the Society:

MICHAEL A. TIGHE, *Secretary*

* * *

Dear Dr. Tighe:

The Office of the Surgeon General has informed me that the United States Public Health Service is in need of an average of twenty-five physicians per month for Coast Guard and War Shipping Administration work, and others for the States Relations Division and miscellaneous assignments.

These physicians will be commissioned in the United States Public Health Service Reserve in the grade of assistant surgeon, or passed assistant surgeon if over thirty-

three years of age Application forms will be available at this office

It will be appreciated if you will bring this matter to the attention of your members or affiliates and urge any who are interested to communicate with me

Sincerely yours,

R P SANDIDGE, *Senior Surgeon*
Medical Officer in Charge

United States Marine Hospital
Boston

COMMITTEE ON MATERNAL WELFARE

ANALYSIS OF CAUSES OF MATERNAL DEATH IN MASSACHUSETTS DURING 1941

MISCELLANEOUS

Of the 5 cases of ruptured uterus that occurred during 1941, the first was that of a thirty four year-old woman who had had no prenatal care during this pregnancy and whose history does not relate whether there had been any previous pregnancies. She was first seen at home as an emergency because of profuse vaginal hemorrhage when about five months pregnant and immediately taken to the hospital by ambulance. Bleeding did not recur. X-ray films taken four days after admission revealed no evidence of fetal bones. Three days later a curettage was performed, the pathological diagnosis of which was "degenerative decidua tissue and hyperplastic endometrium". The patient's temperature rose immediately after the curettage; two days later the abdomen became distended, and death occurred the following day. Autopsy showed peritonitis, with rupture of the uterus on the right, the opening being just large enough to admit the passage of a No 3 dilator. A macerated fetus of five months, with the placenta, was found in the right lower quadrant. The rupture of the uterus was probably traumatic. It is very likely that the pregnancy was abdominal, since it is inconceivable that the fetus and the placenta could have passed into the abdominal cavity through so small a rupture in the uterus. The diagnosis was undoubtedly missed; if the proper diagnosis had been made when the patient was first seen, and a laparotomy performed, this catastrophe could probably have been prevented.

The second patient, a thirty one year old woman who had had one previous miscarriage, first consulted her physician when about four months pregnant; she complained of pain in the shoulder, and several hours later went into profound shock. The diagnosis of ruptured ectopic pregnancy was made, and the patient was sent to the hospital, arriving pulseless and without a demonstrable blood pressure, death occurred very shortly thereafter. Autopsy showed rupture of the uterus, with a four month old fetus still in the sac and a

placenta accreta. The patient's past history was negative, except for the previous miscarriage when three months pregnant. Spontaneous rupture during the fourth month of pregnancy is a most unusual occurrence. It is possible that if the proper diagnosis had been made when the patient was first seen, before she went into shock, abdominal operation would have been successful.

The third patient, a forty-year-old para II who had had excellent prenatal care, went into labor at term. She had very severe pain during labor and was delivered normally ten minutes after admission to the hospital. The baby was dead, and an excessive hemorrhage followed delivery. The patient became pulseless and went into shock, and died ten minutes after delivery of the placenta. Autopsy proved the cervix to be torn deep into one vault, the tear extending into the uterus and broad ligament; the uterine artery on the right was severed. There is no note that pituitrin had been used, and it is possible that the cervix was so filled with scar tissue from the previous delivery that the tear into the broad ligament resulted from the rupture of undilatable scar tissue. This was an unfortunate case but one in which in all honesty the blame cannot be laid to inadequate or overzealous obstetrics.

The fourth case occurred in a thirty six-year-old patient who had had a previous cesarean section for placenta previa. When about thirty six weeks pregnant she complained of severe abdominal pain and was immediately sent to the hospital. A general surgeon was called as consultant, and $\frac{1}{4}$ gr of morphine was ordered. The patient died undelivered two hours later, autopsy showing that the uterus had ruptured along the scar of the previous section. The baby was lying in the abdominal cavity. There was no excuse whatever for this fatality. One quarter of a grain of morphine has never saved the life of a patient with a ruptured uterus.

The fifth patient, a thirty eight-year old primipara who was delivered at term by low forceps, had a severe post partum hemorrhage, examination revealed an incomplete rupture of the uterus. Supravaginal hysterectomy was performed, and the patient was transfused four times. The signs and symptoms of peritonitis developed thirty-six hours post partum, and the patient died of peritonitis on the fourth day. Rarely, the cervix does rupture in a normal delivery and does cause profuse post-partum hemorrhage. From the record one would infer that the operation was not difficult, and hence not the cause of the rupture. Everything possible in the way of treatment was done for this patient. A specific diagnosis was made, the patient was

years. By no means all children constitute serious problems at this period, but it is fair to say that any child worth the raising constitutes somewhat of a problem.

This period has for years been called the "neglected age" of childhood, the cause of the neglect lying quite reasonably in the attitude of the child toward interference with his independent desires; Benjamin,* whose studies at Johns Hopkins University represent the most recent contribution to the problem, calls it the "period of resistance."

Underlying the spite and negativism that make up the chief characteristics of this period, with their varying expressions of misbehavior from thumb-sucking to bed-wetting, from temper tantrums to encopresis and head-rocking, is always a basis of anxiety or inner insecurity—the result of an unsuccessful transition from infancy to early childhood. SECRETARY'S OFFICE

The following letter is published for the information of members of the Society:

MICHAEL A. TIGHE, *Secretary*
* * *

Dear Dr. Tighe:

The Office of the Surgeon General has informed me that the United States Public Health Service is in need of an average of twenty-five physicians per month for Coast Guard and War Shipping Administration work, and others for the States Relations Division and miscellaneous assignments.

These physicians will be commissioned in the United States Public Health Service Reserve in the grade of assistant surgeon, or passed assistant surgeon if over thirty-

were discrete nodules or groups of interstitial cells locally replacing or displacing the seminiferous tubules. Of these there were 13 cases. There were only 3 cases of malignant tumor, which is regarded as an increase of interstitial cells with anaplasia, destruction of tubules and metaplasia. The main features distinguishing these groups are the number and pattern of distribution of the cells. The histologic characteristics, except in the case of malignant tumors with metastases, do not offer enough variation to distinguish between the various types of growth in the presence of the meager clinical data available. Furthermore, there is no satisfactory method of determining the number of interstitial cells in the normal person, because of the variability in the number, size and distribution of the seminiferous tubules, blood vessels, nerves and connective-tissue cells. The "normal number" of interstitial cells is only a visual impression gained by microscopically comparing sections from a series of three hundred and seventy testicles obtained at autopsy and from surgical material. Hormonal changes were relatively few except in children in whom there was precocious puberty with gynecomastia. For the most part ketosteroid determinations were not done. However, in one case report by Mason, the Aschheim-Zondek test was positive in a 1:50 dilution.

The last paper was given by Dr. Shields Warren and was entitled "Bone-Marrow Changes following the Administration of Radioactive Phosphorus." The report was based on 8 patients who had come to autopsy a varying length of time following the administration of radioactive phosphorus, either orally or intravenously, as disodium phosphate. The changes induced in the bone marrow do not differ significantly from those seen in other types of radiation, such as deep x-ray therapy. The changes ranged from very marked depletion of the marrow with almost no abnormal cells and few normal cells to practically no changes, except for minor evidence of damage to cells of the granulocytic series and to some of the megakaryocytes. In most cases there was radiation effect in all marrow elements. As evidenced by examination of the peripheral blood and bone marrow, the general effect of radioactive phosphorus seems to be injury to all marrow elements, with particular effect on the more rapidly proliferating cells. These cases received small doses of low intensity, having been given 2 millicuries at ten day intervals with the dose gradually spreading to once every three to six months. The phosphorus is taken up by the rapidly growing cells, and is accompanied by a drop of the total white-cell count, with a greater percentage of mature cells in the peripheral blood, and a decrease in the number of erythrocytes and platelets. If the dosage is sufficiently small, the effect may be selective on the leukemic cells. In summary, Dr. Warren said that the number of cases is not sufficient for clinical evaluation and that the advantages to date are of minor importance. The latter are as follows: there is no radiation sickness; it is easy to maintain the proper level by either oral or intravenous administration; and treatment can be carried out without bringing the patient to the hospital. It is also quite probable that the dose is concentrated at the point of disease. In the discussion it was brought out that in patients given large doses the effect on the marrow approaches that seen in aplastic anemia and that damaged cells, at least those showing evidence of vacuolization, are found in the circulating blood. Hemosiderin was found in rather abundant amounts, but the amount was not thought to have any clinical significance.

BOOK REVIEWS

Four Treatises of Theophrastus von Hohenheim, Called "Paracelsus." Translated from the original German, with introductory essays. By C. Lillian Temkin, George Rosen, Gregory Zilboorg, M.D. and Henry E. Sigerist, M.D. Edited, with a preface, by Henry E. Sigerist, M.D. 8°, cloth, 256 pp., with 1 portrait. Baltimore: The Johns Hopkins Press, 1941. \$3.00.

The character of Paracelsus was full of contradictions, — violent ones, — which explains why to some he has seemed no better than a besotted charlatan and to others little short of a sainted mystic. The truth — as it so often does — lies in the middle ground. The force of his personality and the originality of his mind cannot be denied. He quarreled so violently and persistently with his professional colleagues that he became an habitual outcast, and many of his writings were denied publication during his lifetime. Yet, he was the founder of chemical therapeutics; he wrote the first treatise on industrial medicine, which discussed miners and their ailments; and he attempted something in the direction of psychiatry and psychology. For the whole list of his contributions, one should consult a book on medical history. All in all his was a great part, and worthy of recollection.

He died four centuries ago, and this book is essentially a memorial volume. The four treatises, each translated by a different hand, are as follows: *Seven Defenseones*, an attempt to justify his views of medicine in opposition to those then prevailing; *On the Miners' Sickness and Other Miners' Diseases; Diseases That Deprive Man of His Reason*; and *A Book on Nymphs, Sylphs, Pygmies, Salamanders*, and so forth, which according to Professor Sigerist affords a good example of Paracelsus's philosophy and theology.

It is pleasant to have something besides hearsay about so important a man. But these treatises are not easy reading. There is much in them that seems obscure, but, as Professor Sigerist remarks in his preface, to translate Paracelsus into modern English would lose much of the original meaning. With all the difficulty, one can discern in the man a trait of shrewd medical observation and a pervading spirit of honesty of mind. And those facts alone are worth the learning.

Food and Beverage Analyses. By Milton A. Bridges, M.D., and Marjorie R. Mattice, M.S. Second edition, thoroughly revised. 8°, cloth, 344 pp., with 40 tables. Philadelphia: Lea & Febiger, 1942. \$4.00.

This second edition, revised and amplified by Professor Mattice after the death of Dr. Bridges, is intended as a reference book for clinicians, students, dietitians, nurses and those concerned with applied nutrition and dietetics. It aims "to provide analytical data on the largest possible number of food factors . . . presented in a readily understandable fashion." The bulk of the material consists of tables of the composition of foods and beverages; but there are also brief general discussions, including chapters on carbohydrates, proteins, fats, water, vitamins, acidity of foods, inorganic salts and alcoholic beverages. There is a glossary of vitamin terms, including the structural formulas of some of the more important vitamins. An extensive bibliography is appended. The figures for food analyses are partly collected from reports in the literature and partly from the authors' own work. They are undoubtedly reliable and as free from error as is humanly possible.

There is great call for such a collection of readily available food and beverage data, attested to by the haziness in the minds of many clinicians concerning food values, and the general tendency to pass all diet-making along to the dietitian. There is also a need for periodic additions to the available data, to include foods and products that are constantly being introduced. Only a few recent single publications meet these needs, notably Chatfield and Adams's *Proximate Composition of American Food Materials* (United States Department of Agriculture Circular No. 549—June, 1940) and the present volume, which is the more extensive.

Although knowledge of the exact composition of foods is most desirable, Bridges and Mattice are quick to point out that many, if not most, of the present analytical data are of necessity anything but exact. Naturally occurring foods vary widely in composition, and such factors as freshness, variable water content, differences in soils, processing and cooking make anything but average values impossible. Furthermore, there are varying factors in the absorption and utilization of some constituents. For example, if one eats spinach, which has a considerable calcium content but is also rich in oxalates, it not only supplies no available calcium but also makes unavailable much of the calcium in other foods ingested at the same time. Finally, there are technical difficulties in chemical analysis, and different workers report widely divergent figures for the same food factors. For example, the English workers, McCance, Widdowson and Shackleton, give figures for the crude-fiber content of foods that are consistently two to eight times higher than those of other workers.

Some data in these tables, although as accurate as possible, are of dubious applicability in dietetics. The acidity of foods as eaten, for example, has no relation to their final effect in body metabolism, as the authors note. Such tables could well be omitted.

If due account is taken of all these pitfalls in the figures, this volume will be of great value to everyone in the field of practical dietetics.

Clinical Hematology. By Maxwell M. Wintrobe, M.D., Ph.D. 8°, cloth, 792 pp., with 167 engravings and 7 colored plates. Philadelphia: Lea and Febiger, 1942. \$10.00.

This book is by far the best English text on the subject of clinical hematology. Crowded into its pages is a wealth of material, all carefully annotated and documented, and replete with references. The completeness of these references—author, title, volume and page—is an indication of the care with which the entire book has been written, from introduction to index, and is confirmatory of the author's reputation as a careful investigator of hematologic and nutritional problems.

In the last few years a wealth of new hematologic texts in English has appeared to fill the large gap formerly present in this field. Some, like that of Kracke, have had excellent illustrations with a rather indifferent text; others, like that of Haden, have quite frankly been written for the general practitioner and as such have been rather elementary in their scope. The monumental four-volume "handbook," edited by Downey, is somewhat unbalanced by its editor's histologic bias, with the result that the clinical articles are often subordinated and given but scant attention. Wintrobe, being primarily a clinician with both physiologic and histologic training, has been able to keep the proper balance between these fields and

has thus produced a first-rate work, which is difficult to criticize.

Descriptions of the blood-forming organs and of the blood cells are complete and free both from the unnecessary polemics regarding derivation of cells and the unique nomenclatures affected by both Osgood and Kracke. The chapter on macroscopic examination of the blood, including the various indices, is new for hematologic texts and reflects Wintrobe's pioneering efforts in this field. Anemia is first considered as a general physiologic problem, the matter of therapy receiving a 50-page section. In the chapters on the various specific diseases, two things stand out: the large number of references,—commonly seen only in monographic articles,—and the consideration of pathology and pathogenesis at the end of each chapter. Ordinarily, one would expect to find possible pathogenetic mechanisms first, pathology second, clinical features third, and treatment last. It must be conceded, however, that Wintrobe's arrangement detracts but little from the value of the book. The chapters on hemolytic anemia, sickle-cell anemia and Mediterranean anemia are excellent, far outranking similar chapters in other texts. Except for hypoprothrombinemia, the hemorrhagic diseases are well covered, as are the leukemias and leukocytic neoplasms. There is a brief but comprehensive chapter on the spleen.

In short, the reviewer has nothing but fulsome praise for Wintrobe's book. One might like a little less didacticism and a little more physiology here and there—but this is captious criticism.

Architectural Principles in Arthrodesis. By H. A. Britain, M.A., M.Ch. With a foreword by Harry Platt, M.D., M.S., F.R.C.S., F.A.C.S. (hon.). 8°, cloth, 132 pp., with 144 illustrations. Baltimore: The Williams and Wilkins Company, 1942. \$6.00.

In this small, superbly illustrated volume, an attempt is made to apply certain principles of architecture to the operation of arthrodesis. It is shown in drawings and photographs that stresses which may lead to failure in an attempted fusion of a joint can be combated by struts made from tibial grafts. The technic of applying such grafts to each joint during the operation of arthrodesis is described. The broad indications for arthrodesis that the author advocates, however, are not accepted in the United States. Here, arthrodesis, except in the case of tuberculosis, is used only as a last resort, but in the author's practice it is the primary operation in many disabilities. The majority of procedures appear to be sound, but the operations that the author performs for arthrodesis of the hip and the ankle seem to make the procedures unnecessarily long and difficult.

Hippocratic Medicine: Its spirit and method. By William A. Heidel. 8°, cloth, 149 pp. New York: Columbia University Press, 1941. \$2.00.

In the days of Hippocrates, Greek medicine, as well as Greek science, was intimately tied in with philosophy. The most significant Hippocratic contribution was, in the last analysis, a point of view—but one so valid that, in essence, it still holds after two and a half millenniums. In this pleasant little book, Professor Heidel discusses the methods, the manners and the posture of medicine in the fifth century B.C. It is not a "must" book, of course, but to read it will be a pleasure and a profit to any physician with a feeling for history and a reverence for the ideals of his profession.

NUMBER 4

THE OCCURRENCE OF COR PULMONALE IN CASES OF BRONCHIAL ASTHMA*

IRVING W. SCHILLER, M.D.,† ABRAHAM COLMES, M.D.,‡ AND DAVID DAVIS, M.D.§

BOSTON

THERE is no uniformity of opinion regarding the role of bronchial asthma in the causation of heart disease. Most authors hold that cardiac complications of this origin are uncommon.¹⁻³ On the other hand, it has been pointed out that bronchial asthma and its sequelae, pulmonary emphysema, often lead to right-ventricular hypertrophy and finally heart failure.⁴⁻⁶ The number of autopsied cases with bronchial asthma reported in the literature, however, is not large, and not all writers have recorded full data on the heart. For this reason, it is of interest to report the cardiac findings in 15 cases of bronchial asthma that came to autopsy. In addition, 54 patients were studied clinically to determine the incidence of cardiac abnormalities of this origin.

ANALYSIS OF DATA

Forty-six of these 69 ambulatory and autopsied patients were men; 23 were women. Fifty-nine (85 per cent) were past forty years of age. Forty-two (61 per cent) had had asthma for ten years or longer. The average duration of the disease was thirteen years. The cases were selected on the basis of the history, physical examination, blood studies and skin tests. A family history of allergy was present in 26 cases (38 per cent). Skin tests were positive in 46 cases (67 per cent), and an eosinophilia of 5 per cent or more was found in 22 cases (32 per cent).

Clinical Data

The histories and physical examinations of the 54 nonautopsied patients were studied to determine the presence or absence of congestive failure. Although in most patients dyspnea was an outstanding symptom, it could not be established that cardiac weakness was a factor except in 1 patient, who

later gave evidence of a cor pulmonale. Likewise, physical examination revealed no evidence of heart failure.

Teleroentgenograms were made in 46 cases. In 34 (74 per cent) the heart shadow appeared normal, in 7 (15 per cent) it was enlarged, and in 5 (11 per cent) the left ventricle was blunted and prominent. Six of the 12 patients with some cardiac enlargement had hypertension; an obvious cause for the enlargement was not found in the remaining 6.

The velocity of blood flow was determined by the Decholin method⁷ in 40 cases.⁷ The average normal circulation time with this method is 15 seconds. The readings in 37 cases (92 per cent) were within normal limits (average 12.8 seconds); in only 3 cases was the circulation time prolonged (22.0, 22.2 and 26.0 seconds, respectively). These 3 patients showed no clinical evidence of congestive failure. The electrocardiograms in 1, however, showed abnormally inverted T waves, and in another there was prolongation of the QRS interval. It has been shown that there is a tendency for the velocity of blood flow to be slightly increased in emphysema,⁸ and this was true in the vast majority of our cases. The occurrence of a prolonged circulation time in these cases, in the absence of any other cause, was considered suggestive evidence of beginning circulatory failure.

Electrocardiograms were available in 46 cases. Fifteen (33 per cent) of these were within normal limits. Thirty-one patients (67 per cent) showed the following abnormalities: prolongation of the QRS interval, 3 cases; inverted T waves in Leads 1 and 2, 7 cases; abnormalities in Lead 4, 3 cases; an abnormally deep Q wave in Lead 3, 2 cases; a deep S wave in Lead 2, 7 cases⁹; and auricular fibrillation, 1 case. Thirteen patients (28 per cent) showed left-axis and 6 (13 per cent) right-axis deviation. A tendency to right-axis deviation was

⁷Decholin Sodium was kindly supplied by Riedel-de Haen, Incorporated, New York City.

further noted in 4 other patients (9 per cent). The only abnormal finding in the electrocardiogram in 6 cases was left-axis deviation, and in 2 cases right-axis deviation.*

Autopsy Data

Autopsy data were available in 15 patients who died during the course of this study. A summary of the clinical and postmortem findings in these

years previously he began to have asthmatic attacks, which were more marked in warm and damp weather. These became progressively more frequent and severe. Two years before admission he began to complain of dyspnea on exertion and attacks awakening him at night. Ten months before admission he began to have swelling of the lower extremities and palpitation on slight exertion. All the symptoms became progressively more marked.

Physical examination on admission showed cyanosis of the lips and cheeks and a uniformly enlarged thyroid

cases is shown in Table 1. Three patients had had bronchial asthma for a period of three years or less, the remaining 12 for six years or longer. Five of the latter died in congestive failure (Cases 1-5), and 4 of these showed predominant hypertrophy of the right ventricle. These 5 patients with congestive failure showed no evidence of valvular disease. The coronary arteries revealed no points of narrowing or occlusion, and the myocardium no areas of fibrosis or infarction.

Six patients (Cases 6-11) died of intercurrent diseases. In 3 of these (Cases 6-8) the heart was normal; 1 patient (Case 9) had hypertensive and arteriosclerotic heart disease, and 2 (Cases 10 and 11) showed an unexplained increase in heart weight. Asthmatic paroxysms played a prominent part in the terminal state in 4 patients (Cases 12-15), and 1 of these showed a slightly dilated right ventricle.

CASE REPORTS

CASE 1. A 53-year-old man was admitted to the hospital on July 11, 1933, complaining of a productive cough, shortness of breath, nocturnal dyspnea and edema. Twelve

*Axis deviation was determined by the angle method: angle below 0° = left axis; angle above 90° = right axis; angle 80 to 90° = tendency to right axis.

gland. The chest was barrel shaped and hyperresonant, and expiration was prolonged. There were numerous rhonchi throughout both lung fields and occasional rales at the bases. The heart sounds were slow and regular, and there was a systolic murmur at the apex. The liver edge was palpable 4 cm. below the costal margin. The blood pressure was 100/55. Roentgen examination showed a transverse cardiac diameter of 18.3 cm. and a chest diameter of 32.2 cm. The laboratory findings were normal except for a white-cell count of 14,200. The basal metabolic rate was +54 per cent on admission, but a subsequent determination was +16 per cent. It was assumed that the patient was suffering from congestive heart failure, probably due to coronary heart disease. A diagnosis of cor pulmonale secondary to bronchial asthma and emphysema was not made.

Total ablation of the thyroid gland was considered with the hope of relieving the cardiorespiratory symptoms. At operation the thyroid gland was found to be considerably enlarged. Early in the postoperative course the temperature rose and the respiratory distress became more marked. In spite of all therapeutic measures, the patient died on August 3.

The surgically removed thyroid gland, although enlarged, showed normal tissue on microscopic examination. There was no evidence of hyperplasia.

Autopsy (No. 33-70). Throughout both lung fields there were many small bronchiectatic abscesses and areas of emphysema. In the upper portion of the left lung there was a particularly large area of emphysema that com-

municated with areas deeper in the lung tissue. Microscopic examination showed extensive fibrous thickening and round cell infiltration of the alveolar septum. The heart weighed 620 gm. The right auricle was tremendously dilated. The wall of the right ventricle measured 1.2 cm and that of the left 1.5 to 2.0 cm in thickness. The coronary arteries showed no atherosclerosis and were patent throughout. There was no fibrin or evidence of infarction.

Case 2 A 58-year-old man was admitted to the hospital on October 21, 1935, complaining of cough, shortness of breath and swelling of the legs. Cough had been present for many years. Three years before admission he began to have paroxysmal attacks of shortness of breath with wheezing, which became progressively more frequent and severe. Two months before admission he noticed palpitation and orthopnea, and 6 weeks later edema of the legs appeared for the first time.

Physical examination on admission showed cyanosis, dyspnea and orthopnea. The chest was emphysematous and there were dullness and coarse rales at both bases. The heart sounds were distant and rapid but regular. The second pulmonary sound was accentuated. There was pitting edema of the lower legs and over the sacrum. The blood pressure was 120/110. The laboratory findings were within normal limits. A diagnosis of congestive failure probably due to arteriosclerotic heart disease was made.

The patient was immediately placed in an oxygen tent digitized and given sedatives. He did not respond to treatment, however, and died the next morning.

Autopsy (No. 35-92) The left lung weighed 500 gm, the right lung 640 gm. Gross sections through the right lower and middle and left lower lobes showed small subpleural areas, 2 to 6 cm in diameter, full of mucopurulent material. Microscopic examination showed dilatation of the small bronchioles and desquamation of the lining epithelium. Surrounding these small bronchioles there was much fibrosis and round-cell infiltration. The heart weighed 520 gm. The myocardium showed no evidence of softening, fibrosis or infarction. The coronary vessels were patent throughout, and their internal surfaces showed only a few small scattered atheromatous plaques. The wall of the right ventricle measured 1.2 cm and that of the left 2.2 cm in thickness.

Case 3 A 60-year-old man was admitted to the hospital on August 24, 1937, because of marked weakness, precordial pain on exertion increasing dyspnea, and peripheral edema of 9 weeks' duration. He had had attacks of bronchial asthma for 12 years, and for many years before this a nonproductive cough. Seven years before admission he had an attack of hemoptysis, for which he was admitted to a sanatorium. Six months later he was seen in the outpatient Allergy Clinic for cough and wheezing. Physical examination at that time showed cyanosis, prolonged and labored expiration, rhonchi throughout both lung fields and crackling rales at both apices. The heart action was slow and regular, and the sounds normal. There were no murmurs. The vital capacity was 1800 cc. Skin tests were positive for house dust. During the next 6½ years the patient was followed in the Allergy Clinic, but in spite of treatment, cough and wheezing continued. Approximately 2 months before admission, dyspnea and weakness became more marked and for the first time swelling of the lower extremities appeared.

Physical examination on admission showed orthopnea, dyspnea and cyanosis. Both lung fields were filled with musical and moist rales. In the right chest, below the axilla, there were amphoric breathing and cavernous crackles. The heart sounds were rapid but regular, there were no murmurs. The blood pressure was 106/68. The liver edge was felt two fingerbreadths below the right costal margin. There was marked pitting edema of both lower extremities to a point below the knees. The white cell count was 23,000, and the blood nonprotein nitrogen 33 mg per 100 cc. An electrocardiogram showed right axis deviation.

In spite of digitalization and an oxygen tent, dyspnea, orthopnea and cyanosis became progressively more marked and death occurred on the 3rd hospital day, following complete circulatory collapse.

Autopsy (No. 37-93) The right lung weighed 710 gm and the left lung 560 gm. The apical surfaces were covered with thick plaques of fibrous tissue. The bronchioles were dilated and ended in saccular dilatations filled with purulent material. Microscopic sections showed a picture of old fibrosis, newly proliferating fibrous tissue and bronchiectatic cavities. The heart weighed 420 gm. The right ventricle appeared to be hypertrophied. The coronary arteries showed a few arteriosclerotic plaques, which did not greatly narrow the lumen. There were no areas of marked fibrosis or infarction. The wall of the right ventricle measured 0.7 to 1.0 cm and that of the left 1.2 cm in thickness.

Case 4 A 51-year-old man was admitted to the hospital on February 20, 1931, because of progressive edema of the lower extremities of 6 weeks duration. Approximately 8 years previously he began to have a chronic cough, which was later associated with wheezing and attacks of asthma. This condition grew gradually worse and was more marked in the fall and winter months. His father who died at the age of 60, had had bronchial asthma. One and a half years before admission the patient was seen in the outpatient Allergy Clinic. At that time physical examination showed cyanosis, expiratory difficulty, a barrel shaped, emphysematous chest and bilateral rhonchi throughout both lung fields. The vital capacity was 1500 cc. The heart sounds were slow and regular. The blood pressure was 120/90. Skin tests were positive for several common inhalants. During the next 18 months the patient was seen in the Allergy Clinic at weekly intervals. In spite of treatment he grew steadily worse, and was therefore admitted to the hospital.

Physical examination on admission showed dyspnea and marked cyanosis, the fingertips showed clubbing, the chest was emphysematous, expiration was difficult and markedly prolonged, and there were rhonchi throughout both lung fields. The heart sounds were slow, regular and of good quality. There were no significant murmurs. The blood pressure was 125/85. The liver edge was felt three fingerbreadths below the costal margin. The legs, thighs and scrotum were markedly edematous. Stereocentigenographic examination showed no significant change in the lung fields. The transverse diameter of the heart, however, was markedly increased. An electrocardiogram showed marked right axis deviation (angle 130°). All the laboratory findings were normal except for a white cell count of 13,200. A diagnosis of congestive failure was made, but the presence of cor pulmonale due to bronchial asthma and emphysema was not suspected.

In spite of treatment, the patient showed no signs of improvement, and on the 5th hospital day he was found

in a state of collapse. Examination of the chest showed signs of consolidation in both lung bases posteriorly. He was placed in an oxygen tent. The temperature rose progressively to 104.0°F., tracheal rales developed, and the patient died on the 9th day after admission.

Autopsy (No. 31-20). There was a small amount of fluid in both pleural cavities. The lungs showed bilateral bronchiectasis with multiple bronchiectatic abscesses. The right lung weighed 1200 gm. and the left lung 590 gm. The right side of the right lower lobe was very firm, and on section this area showed a necrotic hemorrhagic abscess, 4 cm. in diameter and lined by a definite wall. The middle and upper lobes showed smaller but similar purulent areas. The left lung was somewhat collapsed. Throughout the various cut surfaces, especially in the lower lobe, grayish-white, firm raised areas were to be seen. The main bronchioles were distended and increased, and their thickened walls were traced to the periphery. Microscopic examination showed marked fibrosis, and the alveoli were lined by thickened fibrous walls. The bronchi were dilated and filled with pus. The heart weighed 400 gm. The musculature of the right side appeared almost as thick as that of the left. The wall of the right ventricle measured 1.0 cm. and that of the left 1.5 cm. in thickness. The interventricular septum showed no bulge to the right side. The coronary arteries showed no arteriosclerosis. There was no fibrosis or evidence of infarction.

DISCUSSION

The effects of bronchial asthma and pulmonary emphysema on the right side of the heart are difficult to estimate clinically. Before congestive failure has occurred, hypertrophy of the right ventricle is usually not sufficiently marked to make itself evident by x-ray study. On the other hand, when congestive failure is present, the burden of proof is on those who maintain that the bronchial asthma or emphysema is of etiologic importance. Valvular, hypertensive and coronary disease must first be excluded, and to do this autopsy data must be available. The usual method of estimating ventricular hypertrophy by the thickness of the ventricular walls is at best crude, and it is probable that minor degrees of right-ventricular hypertrophy are not infrequently overlooked. This is particularly apt to be the case when heart disease is not the cause of death and the total heart weight is near the upper limits of normal. On the other hand, when at autopsy it is noted that the right ventricle is grossly hypertrophied and the thickness of its wall is well above the usual limits of normal, it is probable that right-ventricular strain of considerable magnitude had been present.

It is significant that many of the autopsied cases of bronchial asthma reported in the literature reveal unmistakable evidence of predominant hypertrophy of the right ventricle. Thus, of 5 autopsied cases with cardiac data reported by Huber and Koessler,¹⁰ 2 had hypertrophy of the right ventricle. Harkavy¹¹ reported autopsy findings in 2 cases. One of these with bronchial asthma of only

six months' duration did not show any cardiac abnormality. The second patient, however, a woman of thirty-four, who had had bronchial asthma for nine years, died of cor pulmonale. Five years before death she began to show progressive edema which reached enormous proportions. At autopsy the heart weighed 525 gm. The right ventricle and auricle were tremendously dilated and somewhat hypertrophied. The left ventricle was normal in size. Rackemann¹² reported a case of fatal asthma in a woman of forty-three with a history of asthma of twelve years' duration. At autopsy the heart weighed 290 gm., but the right ventricle was acutely dilated. MacDonald¹³ reported cardiac findings in 8 autopsied cases. Three showed definite evidence of hypertrophy and in the remaining cases the right ventricle was dilated. Colton and Ziskin⁴ reported autopsy data in 6 cases, and of these 1 showed marked hypertrophy and dilatation of the right ventricle. Sprague⁶ reported 2 cases of fatal asthma with right-sided hypertrophy. Thieme and Sheldon³ recorded cardiac weights and measurements of the thickness of the right and left ventricles in 7 of their autopsied cases. The asthma was of short duration (one or two years) in 3 of these patients. One of the remaining 4 with asthma of long duration showed definite hypertrophy of the right ventricle.

Recently, Kountz, Alexander and Prinzmetal¹⁵ determined the weight of each ventricle separately in 17 cases of pulmonary emphysema. Since the end result of severe bronchial asthma is pulmonary emphysema, their data are germane to this problem. The cardiac findings were within normal limits in 7 cases. The remaining 10 showed predominant hypertrophy of the right ventricle. These authors reproduced similar cardiac findings in 19 dogs after the production of pulmonary emphysema experimentally. Eleven animals showed dilatation and predominant hypertrophy of the right ventricle.

The duration of bronchial asthma in 3 of our 15 autopsied cases was three years or less; the hearts were normal. In the 12 other cases, in which asthma had existed for six years or longer, 4 patients (33 per cent) showed unmistakable effects of right-ventricular strain and died in congestive heart failure. Heart failure may have been related to asthma in 1 other patient (Case 5), who showed no obvious hypertrophy of the right ventricle. Injection dissection studies by the Schlesinger technic¹⁴ in this case revealed no evidence of coronary disease. The electrocardiogram showed right-axis deviation.

Although our group of 54 cases studied only clinically showed with one exception no evidence of heart failure, the electrocardiographic examina-

tion revealed many abnormalities that can probably be ascribed to myocardial disease. This finding is in accord with the studies of Unger,¹⁵ Kahn,¹⁶ Anthony¹⁷ and Colton and Ziskin.⁴ The most significant finding was right-axis deviation in 13 per cent of the cases (angle above 90°). In another 9 per cent, a tendency to right-axis deviation was present (angle 80 to 90°). This is particularly significant, for it has been shown that right-axis deviation producing an angle of 90° or over is regularly associated with predominant hypertrophy of the right ventricle. In a series of 68 normal hearts, for example, Proger and Davis¹⁸ did not find a single case with an electrical axis above 80°. Of the patients in whom asthma was present for ten years or longer, the incidence of right-axis deviation was 18 per cent. Apparently, the longer the duration of asthma, other factors being equal, the greater the strain on the right ventricle and the higher the incidence of right-axis deviation. Right-axis deviation of the magnitude noted cannot be accounted for by alteration in the position of the heart due to a low diaphragm. These changes in the electrocardiogram are in harmony with the occurrence of right-ventricular hypertrophy at autopsy.

It would appear, then, that cardiac complications in the course of bronchial asthma and its sequelae, emphysema and bronchiectasis, are much commoner than is generally believed. When circulatory failure first appears, its diagnosis is often made difficult by dyspnea of emphysematous origin. Although some patients with cor pulmonale show edema for many months before death, others do not. In Case 2, for example, there was progressive dyspnea for three years. Peripheral edema and pulmonary congestion, however, were present for only a few weeks before death. Also in Cases 3 and 4 the presence of edema before death was of short duration. Thus, rapidly progressing heart failure may appear suddenly in patients with cor pulmonale.

SUMMARY AND CONCLUSIONS

The heart was studied in 69 patients with bronchial asthma; the autopsy findings in 15 of these cases are analyzed.

Electrocardiographic abnormalities, indicating right-ventricular strain and myocardial damage, were noted in a comparatively high percentage of patients with chronic bronchial asthma.

Five of 12 autopsied cases with bronchial asthma of six or more years' duration died in congestive failure, and 4 of these showed predominant hypertrophy of the right ventricle.

Cor pulmonale due to chronic bronchial asthma is a commoner disorder than is generally recognized.

A DIETARY STUDY OF SUBJECTS FROM UPPER INCOME GROUPS*

HERBERT T. KELLY, M.D.,† AND MYRTLE SHEPPARD, B.A.‡

PHILADELPHIA

THIS dietary study was undertaken in 1940 because so little has been done on the dietary pattern of private patients. We decided, therefore, to analyze the diets of private patients to determine their daily intake of dietary essentials. We also considered it worth while and interesting to record the number of adults, from the same income level, but not under active medical supervision, who daily consumed the foods that the Committee on Foods and Nutrition of the National Research Council has stated every person must have to secure the required amounts of dietary essentials.

MATERIAL AND METHODS

Two hundred and twenty-five patients, 92 males (9 of whom were physicians) and 133 females, of various ages, from the upper income brackets and representing a cross-section of private patients attending our clinic, were selected for this study. In addition, 223 persons (20 of whom were physicians), from various upper-middle-class groups that we addressed from time to time, answered questionnaires regarding their dietary pattern; they were not, so far as we knew, under medical supervision.

For each of the 225 patients, we had a complete dietary history, including food habits, dislikes, intolerances and cravings, and a seven-day dietary calculation formulated on the basis of a diet questionnaire filled out by each patient—including the amounts and kinds of all food and liquid ingested, both during and between meals, and the mode of preparation of food. The patients were given these questionnaires when they first presented themselves with their complaints, and were told to fill them out meal by meal for a week, expressing quantities in cupfuls, tablespoonfuls, teaspoonfuls, ounces or number of units, such as one tomato, half a tomato and so forth. When they returned a week later with their questionnaires filled out, we went over them with the patients, making certain that salad dressings, sugar and cream, and the like were recorded. While reviewing their diets, we also suggested dietary changes in line with their specific ailments.

Since exact weights of the amounts of food con-

sumed were not recorded, we realize that our findings may not have been completely accurate. However, we are of the opinion that, had we asked the patients to weigh their food, we should have had little co-operation. Furthermore, although the amounts recorded were not completely accurate, we believe that we have a true picture of the patients' dietary patterns and that in these patterns dietary deficiencies were evident. Whether a diet contained 3800 or 4000 international units of vitamin A made little difference, the important fact being that the diet was deficient in vitamin A.

The diets were calculated to determine the amounts of protein, fat, carbohydrate, calories, vitamins A, B₁, B₆ and D, ascorbic acid, riboflavin, niacin, calcium, phosphorus, iron, copper, potassium, sulfur, magnesium, manganese, sodium, chlorine, acid-base, fiber and water. The food values were obtained chiefly from Bowes and Church's *Food Values of Portions Commonly Served*, both the third and the fourth edition.¹ While we were still in the process of calculating diets, Bowes and Church published the fourth edition of their book and we proceeded to make our calculations from this edition. In addition to Bowes and Church's text, we used Hawley and Maurer-Mast's.² We modified many of Bowes and Church's figures in their third edition in accordance with Munsell's³ work, and went to the original literature^{4, 5} for calculations on the trace minerals. Unfortunately, our data for the trace minerals and for niacin and vitamin B₆ were not complete because of lack of information on their content in many foods. While we were using Bowes and Church's third edition, we expressed vitamin B₁ and riboflavin in terms of international units and Sherman-Bourquin units respectively; when we went to their fourth edition, we used their revised method of expression—vitamin B₁ and riboflavin in micrograms.

After the patients' diets were calculated for their weekly intakes, we divided by 7, to determine the average daily intakes. We did not calculate daily intake of trace minerals, vitamin B₆ and niacin, since our data were incomplete; we merely computed the weekly intake of these factors. The diets were then scored for each of the dietary essentials—protein, calories, vitamins A and B₁, riboflavin, ascorbic acid, calcium, phosphorus and iron—on the basis of the standards set up by the Committee on Foods and Nutrition of the National

*This study was aided by a grant from White Laboratories, Incorporated, Newark, New Jersey.

Research Council,¹ taking into consideration age, sex and activity (Table 1). These are tentative allowances and can be met by a good diet of natural foods, which will also provide other minerals and vitamins whose requirements are less well known.

A deviation of 5 per cent was allowed for all the essentials except calories, for which we allowed 10

tively and if the amount recorded was "little," as 4 gm respectively. Since we could not calculate the amount of vitamin D derived from sunshine, we merely recorded the amount of vitamin D in the weekly diet.

We then accumulated our data on these 225 diets to determine how many were deficient in vitamin A, how many were deficient in vitamin

*Requirements may be less if provided as vitamin A₁ or if provided chiefly as the provitamin carotene.

†1 mg thiamine = 333 int. units. 1 mg ascorbic acid = 10 int. units.

‡Needs of infants increase from month to month; the amounts given are for approximately 6 to 8 months. The amounts of protein and calcium needed are less if derived from breast milk.

§Allowances are based on needs for the middle year of each group (7, 8, 9 and so forth) and for moderately active.

¶Vitamin D is undoubtedly necessary for older children and adults; when not available from sunshine it should be provided probably in minimum amounts recommended for infants.

per cent. We established the following standards for the other constituents of the diet in line with scientific research: carbohydrate, 50 to 60 per cent of the total calories⁷; fat, 20 to 35 per cent of the total calories⁸; acid base, both the same or slightly more acid than base⁹; fiber, 50 to 63 gm¹⁰; and water, 2800 cc¹¹. For carbohydrate and fat, we allowed a 5 per cent, and for fiber and water, a 10 per cent deviation. Since our data were incomplete for the trace minerals, vitamin B₁ and iron, we did not score the diets on these components. Regarding sodium and chlorine, we questioned the patient concerning the amount of salt used. If the amount was stated as "average," we estimated the salt intake, in addition to the amount found in food, as 6 gm of sodium and 6 gm of chlorine daily; if the amount was "large," we estimated the daily sodium and chlorine as 8 gm respec-

tively and so forth, and to determine their degree of deficit. For the trace minerals, vitamin B₁, iron and vitamin D, we expressed our findings in terms of numerical ranges.

We also recorded how many diets had only one deficiency, how many had two deficiencies and so forth. In accumulating these data, we considered only protein, calories, calcium, phosphorus, iron, vitamins A and B₁, ascorbic acid and riboflavin, since these are the dietary factors that are principally concerned. We have eliminated the other factors for the following reasons: fat and of calcium, because much about the ill or cent of the drate, acid whether forming

in human nutrition¹²; fiber, because individual needs and methods of cookery vary greatly and influence the requirement and the content of fiber would be deficient in vitamin B₁; if the amount of meat ingested was small, the diet would probably be deficient in riboflavin (unless a good deal

*Patients eating between meals numbered 94, or 42 per cent; this figure does not include those who ate fruit, fruit juices or milk, which do not interfere with appetite.
†In addition, 161 patients, or 71.5 per cent, had an acid-base imbalance; of these, 155 had more base-forming and 6 more acid-forming foods.

in foods; and other factors, because the data were incomplete. After analyzing over two hundred diets, we could deduce merely from looking over the weekly diets whether or not the dietary essentials were provided in adequate amounts. For example, if a of milk was consumed), phosphorus and iron; and if there were no citrus fruits or raw cabbage or green pepper or raw green leafy vegetables, the diet would be faulty in ascorbic acid. We then analyzed the dietary "yardstick" adopted during the National Nutrition Conference,¹³ and

FIGURE 1. Summary of Patients' Dietary Imbalances.

pint of milk was not ingested daily, the diet would be deficient in riboflavin, and probably also in calcium, since the amount of calcium present in other sources, such as vegetables, is not adequately utilized and is variable, depending on the calcium content of the soil; if white bread was taken instead of enriched white or whole-wheat bread, the diet found that a daily consumption of at least one pint of milk, three slices of whole wheat (or enriched) bread or its equivalent in whole-grain cereal, one serving of meat, one egg, two servings of vegetables, two servings of fruits (one of which should be a citrus fruit) and two and a half tablespoonfuls of butter, cream or fortified oleomargarine,

provided the following essentials: 1500 calories, 62.2 gm. of protein, 0.85 gm. of calcium, 17.2 mg. of iron, 4300 international units of vitamin A, 1400 microgm. of Vitamin B₁, 80 mg. of ascorbic acid, and 1700 microgm. of riboflavin. A comparison with the standards reproduced in Table 1 indicates how many of the dietary essentials are furnished by this dietary yardstick, which supplies less food than the average person ingests.

We then decided that it would be worth while to compare the diets of patients and healthy persons, to obtain a picture of the dietary deficiencies of the upper income groups. We therefore distributed questionnaires to members of lay and professional groups whom we addressed from time to time, asking them to record "yes" or "no" to questions concerning their daily ingestion of the foods listed in the dietary yardstick. The answers to these queries were recorded and compared with the dietary pattern of the patients.

DIETARY FINDINGS IN PRIVATE PATIENTS

The dietary computation in 225 private patients is shown in Table 2.

Figure 1 illustrates graphically the percentage range of these dietary deficiencies and faulty habits. The values for other factors are expressed in numerical ranges on a weekly basis (Table 3). Although little is known of the functions in the body of the trace minerals and vitamin B₆, clinical evaluation of such factors will undoubtedly be accomplished in the future, and perhaps, these ranges will be of value to other investigators. However, it is known that manganese is necessary for the synthesis of vitamin B₁ and ascorbic acid, that a deficiency of copper may produce anemia, and that excess fluorine causes dental caries.

It should be noted that the diets of the majority of patients were high in fat (Fig. 1). We believe this excess is linked with large amounts of money to spend for food, since butter, cream, creamed vegetables, rich desserts and the like are relatively expensive. We have found that persons in the lower income levels cannot afford to spend large amounts of money on fat, and as a result their diets are significantly lower in fat.

Diets of Physicians

Among the 225 patients were 9 physicians whose diets were as bad as those of the other patients. Two of the 9 were deficient in protein; all had an excess of fat; all were deficient in carbohydrates; 7 were deficient in calories; 4 were deficient in vitamin A; all were deficient in vitamin B₁; 8 were deficient in riboflavin; 1 was deficient in ascorbic acid; 4 were deficient in calcium; 1 was deficient in phosphorus; 5 were deficient in iron;

4 had acid-base imbalance; 7 were deficient in water; and 3 ate between meals.

Preparation of Food

According to the patients' answers to questions regarding vegetable cooking, in most cases the veg-

etables were not prepared or cooked properly. A good deal of water was used in cooking, the remaining pot liquor was not used, potatoes were not cooked in their jackets and so forth. Therefore, in most cases, because of losses in cooking, the diets of the patients undoubtedly contained less vitamins and minerals than were found on calculation.

Multiplicity of Dietary Deficiencies

It must be remembered that vitamin deficiencies are multiple and are rarely found alone, not only because a diet that is deficient in one factor is usually deficient in more than one factor, but also because a deficiency of one factor causes a greater strain on the other factors and, in turn, brings about an increase in the body's demand for these.

On compiling the data concerning the number of diets that were deficient in one or more of the essential factors,—protein, calories, vitamins A and B₁, ascorbic acid, riboflavin, calcium, phosphorus and iron,—we found the following: diets deficient in 0 factors, 28, or 12 per cent; diets deficient in 1 factor, 21, or 9 per cent (1 physician);

that at the time this survey was made only a small fraction of the white bread sold on the market was enriched. Yet the figures concerning the general consumption of whole wheat or enriched bread belie this statement. We are certain that the non-medical subjects of our survey often answered "yes" to many questions in the questionnaire be-

FIGURE 2 Incidence of Number of Essentials in Which Patients' Diets Were Deficient

diets deficient in 2 factors, 42, or 18 per cent; diets deficient in 3 factors, 41, or 18 per cent (4 physicians); diets deficient in 4 factors, 23, or 10 per cent (2 physicians); diets deficient in 5 factors, 21, or 9 per cent; diets deficient in 6 factors, 16, or 7 per cent; diets deficient in 7 factors, 18, or 8 per cent (2 physicians); and diets deficient in all factors, 15, or 7 per cent.

Of the 21 diets deficient in 1 factor, 9 were deficient in vitamin B₁, and 8 in riboflavin; of the 42 diets deficient in 2 factors, 36 were deficient in both B₁ and riboflavin (Fig. 2).

DIETARY FINDINGS IN PRESUMABLY HEALTHY PERSONS

We endeavored to determine how closely the dietary pattern of our group of 225 private patients conformed with that of a group of 223 non-medical subjects of similar socioeconomic status. To accomplish this, we recorded the answers of the "nonpatients" to a series of questions concerning their daily ingestion, in proper amounts, of the foods listed in the dietary yardstick.¹³ The data thus obtained are presented in Figure 3.

In a survey of this sort, many errors are incurred. For example, we are convinced that not many people eat whole-wheat or enriched bread. This has been proved by the calculation of the diets of our patients and also by the fact that the consumption of whole-wheat bread is very small and

cause they knew the answer should be "yes." However, for purposes of comparison, we found these questionnaires valuable.

DISCUSSION

In this study we observed that more of the diets of the private patients were deficient in vitamin B₁ and riboflavin than in any of the other vitamins or minerals. A recheck of the foods eaten or not eaten revealed that daily quotas of milk (one pint), whole-wheat or enriched grain products (two or three slices of bread or its equivalent in cereal), eggs (three to five a week) and fruit (two servings) were supplied by the diet *less often* than those of other nutritionally essential foods were.

Since the diets were often low in milk, they were of necessity low in riboflavin (and also calcium), and being low in whole-wheat or enriched grain products, they were low in vitamin B₁. The lack of eggs is not clearly illustrated by a definite deficiency in the diet, for the various minerals and vitamins contained in eggs can be supplied by other foods. In most cases, one serving of fruit was consumed daily. The lack of a second serving did not result in a specific dietary inadequacy, since the large consumption of vegetables made up for this lack. Because the consumption of fat, citrus fruits and vegetables was high, there were but few deficiencies in vitamin A and ascorbic acid. Since the protein intake in

many cases was low, iron and phosphorus deficiencies appeared.

A comparison of the patients' diets with the diets of nonpatients indicated that the dietary

70 disliked milk; and of 206 with euclorhydria (normal hydrochloric acid content), 40 disliked milk. However, we believe that some still undetermined condition in the large number of people

FIGURE 5 Summary of Nonpatients' Daily Dietary Pattern

pattern of the latter was about the same as that of the former. In the questionnaires returned by the nonpatients, there were more "no" answers to queries concerning adequate consumption of milk, eggs, fruit and whole-wheat or enriched grain products than to those concerning the other essential foods. The water intake was low in both groups. If these diets could be calculated quantitatively, deficiencies of riboflavin and vitamin B₁ undoubtedly would rank highest. Most of the nonpatients obtained their one serving of meat daily, but only one serving of meat each day does not satisfy the protein requirement because the milk and, possibly, the eggs are needed to supply the balance.

After questioning patients and nonpatients, we found that there were many reasons why people did not drink milk. Milk was considered fattening, milk made them constipated, milk gave them indigestion and so forth. We believed that some somatic condition caused an intolerance to milk and thought that this intolerance might be linked with a condition of achlorhydria. We therefore made a survey of 597 patients who attended this clinic, checking the patients' dislike for milk and the hydrochloric acid content of their gastric juices. Unfortunately, there seemed to be no correlation. Of 80 patients who had histamine achlorhydria, only 20 disliked milk; of 311 with hypochlorhydria,

who dislike or do not tolerate milk is correlated with such intolerance.

SUMMARY AND CONCLUSIONS

The diets of 225 private patients from the upper income level, 9 of whom were physicians, were calculated.

Questionnaires regarding dietary pattern were filled out by 223 persons from the upper income level, 20 of whom were physicians, but none of whom were under direct medical supervision.

Among the private patients, the most prominent dietary deficiencies were in vitamin B₁ and riboflavin—76 per cent of the patients being deficient in vitamin B₁ and 77 per cent deficient in riboflavin.

Among those subjects not under direct medical supervision, milk, eggs, fruit and whole wheat or enriched grain products were the foods most frequently found lacking. This dietary pattern was similar to that of the patients, and on calculation, the diets of these 223 individuals would undoubtedly also be shown to be primarily deficient in vitamin B₁ and riboflavin.

THE TREATMENT OF COMMON SKIN DISEASES*

BEATRICE MAHER KESTEN, M.D.†

NEW YORK CITY

THE skin conditions that we see most commonly at the Vanderbilt Clinic and on the wards of the Presbyterian Hospital are acne, psoriasis, dry chapped skin, coccal infections, fungus infections and allergic dermatoses.

The first step in the treatment is the diagnosis. In addition to the appearance of lesions, there are three factors of distinct diagnostic help: the patient's story—of particular importance in the allergic group; laboratory tests, such as the direct examination of the involved skin for fungi or cocci and the use of skin tests in the diagnosis of the allergic group; and the therapeutic test, that is, specific treatment for the most likely diagnosis.

ACNE

A very mild acne is almost normal with the onset of puberty. Mild to moderately severe acne can be well treated by the general practitioner, but severe cystic and nodular acne requires the specialist's care. The treatment may be divided into local and systemic. Local care includes meticulous and prolonged work. At bedtime the areas involved should be thoroughly scrubbed with either tincture of green soap or sulfur soap. The comedones should be expressed with a blackhead remover and then sulfur—either Lalotin (Lascoff) or Sulpholac (Alba)—should be massaged into the areas in which the blackheads have been removed. In the morning the sulfur is removed by thorough scrubbing with warm water and soap. This is followed by rinsing with cold water. Powder may be used, but all creams and greases should be avoided. The systemic treatment of acne should include normal adequate caloric intake and the avoidance of chocolate, iodine, and an excess of sweets and greasy foods; a unit of exercise; and protection from direct sunlight and the use of a system of protection, such as

constipation or dysmenorrhea. The discrete use of endocrine preparations in patients having clear-cut menstrual difficulties is worthy of trial.

PSORIASIS

As in the treatment of acne, the therapy of psoriasis resolves itself into local and systemic. Dermatologists no longer believe that the patient with psoriasis need go about feeling that nothing can be done for him. Much can be done with purely local therapy, such as crude coal tar and the ultraviolet treatment of Goeckerman.¹ However, there is an increasing literature suggesting that psoriasis is a disturbance of lipid metabolism. Since 1933 a number of reports have appeared in the German literature on the successful treatment of psoriasis by rigid adherence to a diet not exceeding 20 gm. of fat daily. Later Dragstedt and his co-workers² reported that 17 out of 23 patients became free from psoriasis following the ingestion of lipocaic. This lipotropic substance, which is isolated from the pancreas, prevents or cures the fatty liver that develops in depancreatized dogs maintained on insulin. Since 1939 we have been trying various lipotropic substances, such as crude liver, rice polish, yeast concentrate, soy-bean phosphatides and defatted wheat germ, in the treatment of psoriasis. With the use of the last two we have had astonishingly good results, particularly in the early type of lesions. The soy-bean phosphatide preparation that we have used is Lexo Cookies (American Lecithin Company); the patients eat from two to five of these daily. The defatted wheat germ is called Vio-Bin (Vio-Bin Corporation); one to two tablespoonfuls are eaten daily.

Along with the lipotropic substances the local medication has been one of the newer tar preparations—3 per cent Nu-kol-tar (Benet) or 5 per cent Neo-tar (Lascoff) ointment. Many dermatologists use one of the di-oxyanthralin derivatives, such as 0.1 to 0.5 per cent Anthralin (Abbott) ointment.

Columbia
of Physi-

Two generalizations may be made concerning the local treatment of psoriasis. In an acute outbreak only soothing applications should be used, and when the eruption is chronic the lesions should be stimulated with one of the preparations mentioned above. Furthermore, at the beginning the various medicaments should be of average or below-average strength, and the strength increased if necessary; for example, one may begin with 0.1 per cent Anthralin and progress to 0.5 per cent. The older vehicles—lanolin, benzoated lard, petrolatum and so on—are being rapidly replaced by wetting agents in water-soluble bases. In these may be incorporated most local medicaments. They are nongreasy, much more penetrating, and wash off readily. At present there are three excellent ones: Solucreme (Lascoff), Hydrosorb base (Abbott) and Mull-sol (Hickok).

DRY, CHAPPED SKIN

Dry, chapped skin is very prevalent in the winter time among people with rather thin skins, and those who wash their hands frequently, such as physicians. Sometimes in addition sharply defined patches of eczema develop on the extremities.

The skin should be treated gently. Soft water should be used if available. Mild or superfatted soaps, or the newer detergents, such as Laval (Hickok) and Terses (Doak) are to be preferred. They are less hard on the skin than the ordinary soaps. The soap should be rinsed off and the skin carefully dried, and anointed with oil or cold cream at bedtime. Vitamin A is almost a specific for very dry skin. It is well to stress foods high in vitamin A and in addition to prescribe 75,000 units of vitamin A a day for a few weeks and then reduce it gradually to 25,000 units a day for a few months.

COCCAL INFECTIONS

For staphylococcal and streptococcal infections of the skin—the commonest, perhaps, being impetigo—treatment with sulfathiazole is simple. Formerly a child with such an infection was excluded from school for weeks, but now it is possible for him to return to school within three or four days. One can use either 5 per cent sulfathiazole in a water-soluble base containing a wetting agent, or, if glycerin is available, about 8 parts of warm glycerin to 1 part of sulfathiazole. Either of these should be applied to the lesions every three or four hours.

We have not had good results with the local use of sulfonamides for boils. This is understandable because of the presence of pus.

For chronic, recurrent boils, dermatologists have a therapy different from that of surgeons or roent-

genologists. In the few cases which reach the dermatology clinic we have found staphylococcal toxoid of remarkable benefit. Its use seems logical because the patient has insufficient resistance to an organism found on the skin. An effort is made to stimulate antitoxin production. Intradermal injections of staphylococcal toxoid (Lederle) are given three times a week. The average initial dose is 0.1 cc. of a dilution containing 1000 necrotizing units per cubic centimeter. The dose is increased by 0.1 cc. each time up to 0.7 cc. Then the next stronger dilution (10,000 units) is used and the course is repeated.

With this type of therapy, the boil may come to a head or may be reabsorbed. Usually no more boils occur after the patient has had a few injections.

FUNGUS INFECTIONS

It has been suggested that the best way to cope with superficial fungus infections is to let everyone have such an infection and learn to live with it. There are two types of causative organisms; dermatophytes, affecting the skin, hair and nails; and yeastlike fungi, the monilias, affecting the skin, nails and mucous membranes.

Perhaps the most effective therapeutic agent is gentian violet. If there is a tender, excoriated or fissured area, a 2 per cent aqueous solution can be used. If not, 2 per cent gentian violet in 25 per cent alcohol is preferable. Once the lesion becomes chronic, a medicament is necessary that will cause exfoliation. Whitfield's ointment is as good as any. For a fungicidal powder, B.F.I. (Mulford), is acceptable.

Reinfection in ringworm infection is probably not very common. There is, rather, a persistent infection, the site being usually the nails of the great toes. If they are serrated, discolored, too thick or too thin, the fungus may be there, and it is well to keep on treating the nails with alcoholic gentian violet.

For the differential diagnosis, it is quite easy to obtain the fungus or the yeastlike organism on culture or to recognize it by direct slide examination. When it is a question of whether the condition is a fungus infection, contact dermatitis or something else, one should take advantage of this laboratory procedure.

With ringworm infections the stockings should be sterilized. Of course, cotton is easily sterilized, but silk or wool is not. The best thing to do is to launder the hose and press them on the wrong side with a hot iron. Shoes do not need to be sterilized if stockings are worn. Bedroom slippers

can be discarded, or sterilized by placing small open jars of formalin in them for a few hours.

ALLERGIC DERMATOSES

Drug Eruptions

Drug eruptions are becoming an increasing problem. There are about two hundred drugs in common use. Unfortunately, any drug may produce an eruption, and practically every known dermatologic condition can be produced by them. A few of them are characteristic. The diagnosis of a drug eruption is made by its sudden appearance, its symmetrical distribution, its extensiveness in comparison with the systemic disturbance, and its brightness.

The history of drug ingestion is sometimes unobtainable; however, the patient has usually been taking the drug for some time. It seems desirable to dispense with some of the drugs now in use, at least some of the sedatives. A walk around the block or a hot bath may be advised instead. The treatment consists in prohibiting the use of the drug and in allaying the itch with sodium bicarbonate baths and calamine lotion.

There are few specific treatments for drug eruptions, with the exception of bromide and iodide eruptions, for which we give sodium chloride. In persons known to be sensitive to arsphenamine, it has been possible to give vitamin C prophylactically. Even after the eruption is present, the use of vitamin C is helpful.

Allergic Eczema

Allergic eczema is commonly seen in infants. It occurs on the flush areas, over the head and neck, and it may become widespread. It may clear up or persist. When it recurs in early childhood, it has no very characteristic distribution except that it is symmetrical and patchy. In adolescence and adult life, a characteristic picture is present: it is perfectly obvious that the skin has been scratched. The eczema occurs on the face and neck and in the antecubital and popliteal creases. For these adults with persistent eczema, dermatology clinics have little to offer. But we are anxious to treat the infant or the child with an eczema that has persisted more than six months in order to determine the substances to which he is sensitive.

Allergic eczema is primarily a gastro-intestinal sensitivity and, unfortunately, the infant is usually sensitive to the foods he eats: milk, most; egg white, cow's milk, wheat, or corn; chocolate, so on.

The most helpful clue is the child's history. The physician will say that shortly after

child refused it. She insisted on it, and the rash developed. Or a mother will say, "Almost from the start, the child didn't like that, cried after eating it, had diarrhea, and then broke out." A careful history is of even more value than skin tests.

Testing the skin to common foods is of value. It is a laboratory procedure, and one must not depend on it too much. If one has the good fortune to obtain a positive skin test, it means the child is or was sensitive to that food, and such a sensitivity may be extremely significant.

Of greatest value is the use of elimination diets. They were first brought out by Rowe,³ and have been expanded and changed by investigators since that time. Thus, a child with severe eczema, on whom no testing can be done, can be placed on an almost synthetic diet. For milk, one can substitute a soy-bean preparation — Sobee (Mead-Johnson) or Mull-soy (Borden) — that is perfectly adequate. Crystalline vitamins A and D may be given, and corn meal or rice as a cereal. When the child improves on this regimen, a new food may be added at three-day intervals. As one continues with additions to the diet, there may be a recurrence of eczema. When this happens the last food added is eliminated. With painstaking care, it is quite possible to determine to which foods a child is sensitive and to eliminate them or desensitize him to them. If a patient is found to be sensitive to an important food, oral desensitization is readily accomplished.

The person with allergic eczema has the ability to become easily sensitized, and if he is not treated vigorously in early life, multiple sensitivities occur. The allergic infant with eczema, at least for the first year, is probably sensitive only to foods, and usually not to very many. After the first year, he acquires sensitivities to other foods and substances, such as wool and silk and bacteria. He is always scratching his skin so that it is chronically inflamed and the patient becomes increasingly sensitive, his sensitivity becoming an almost insurmountable barrier in adult life.

If one is carrying on a diet like the above only bland ointment is necessary. The child is given a standard diet, and a saline is applied.

If one prefers not to use the above diet, one may use a standard diet. There are many preparations of desensitizing agents.

mot

'tis

- sk

with normally innocuous substances. This sensitivity is not hereditary and the lesion is generally localized at onset to the exposed areas. Unfortunately, as with the drug eruptions, there is almost no substance to which the skin may not become sensitized; the commonest such substance is poison ivy.

The diagnosis of contact dermatitis is often made through the history. The use of patch or contact tests is very helpful. It is not necessary to have any elaborate setup for this type of testing. The suspected substance should not irritate the normal skin (one can put a patch on himself first, and then try it on the patient). For example, if the patient is thought to be sensitive to turpentine, one can make a 1 per cent solution of turpentine and put it on the normal skin, cover it with a piece of adhesive tape, and leave it on for twenty-four hours. If he is sensitive to it, an erythema with vesicles will appear at the test site.

The treatment depends on the stage of the eruption. If the eruption is acute, wet dressings or baths are indicated. If it is subacute, lotions or pastes are used.

It has been shown that almost anyone can become sensitive to poison ivy. Usually the person who pulls it up and says, "Nothing ever happens to me" is the one who finally gets the worst attack.

The best approach to the problem is: first, avoid poison ivy; and, second, if you come in contact with it, do something about it as soon as possible. The chances are that if the sensitizing oil is removed from the skin within four hours, one may not get an attack. The affected area should be thoroughly scrubbed with brown soap and water, rinsed well, and sponged off with alcohol.

If soap and water are not available, the ivy may be neutralized by smearing the skin with the juice of the plantain or jewel weed.

If one is susceptible to ivy and unable to avoid it, desensitization is indicated and is often very effective. It may be accomplished by either the oral or the intramuscular route. For oral desensitization the 2 per cent tincture of the poison-ivy toxin is given, beginning with 1 drop and increasing by 1 drop daily up to 1 teaspoonful. This is continued throughout the season. The intramuscular injection should be preseasonal, and usually four injections at weekly intervals suffice.

MEDICAL PROGRESS

ABDOMINAL SURGERY

ARTHUR W. ALLEN, M.D.*

BOSTON

SINCE the effects of trauma inflicted in warfare is, at the moment, uppermost in our minds, it seems appropriate that this progress report be limited to abdominal injuries. Although reports from previous wars and civilian practice have been helpful in determining the best methods of treatment in certain types of abdominal wounds, the classic one, used as a base line in recent years, is the masterful contribution by Wallace.¹ To him, we owe the careful compilation of data collected from the actual experience of the surgeons working under his direction in World War I. Many previously disputed points regarding the management of abdominal wounds were settled. In the present war, most of our information regarding

this subject has come from British sources. This is probably due largely to the breakdown in communications and lack of free exchange of journals, but there is some likelihood that political restriction on such information has played a role.²

In this "total war," we are faced not only with the problem of wounded combatants but with that of injured civilians regardless of occupation, age or sex. This type of warfare is unique in the memory of man, as are the agents of destruction used. The complete change in the character of the machines of war in the past twenty-five years has brought about new kinds of wounds along with a type of destruction of life and property hitherto unknown. Almost completely surprised and unprepared for such extensive and varied injuries, Great Britain has met the situation in a most efficient and gratifying manner. To her, we in America owe the opportunity for preparedness,

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual, Vol. III, 1942* (Springfield, Illinois: Charles C. Thomas Company, 1942. \$5.00).

*Chief, East Surgical Service, Massachusetts General Hospital; lecturer in surgery, Harvard Medical School.

even though progress in this direction has, at times, seemed unbearably slow.

The most comprehensive article so far written on the types of abdominal wounds suffered by the British in the present conflict is one by Gordon-Taylor³; it was presented by him before the Clinical Congress of the American College of Surgeons in Boston (November 3-7, 1941). In the present report he will be quoted often and liberally, since he has brought to us many important details, particularly those concerning the abdominal injuries resulting from bombing. It is my purpose to stress these civilian casualties, since those of us left at home must gather information in advance of such a catastrophe; also, problems relating to the management of abdominal wounds occurring in civil practice are always important. From various reports from the war zones, and especially from the excellent military manual on abdominal injuries prepared by Storck,⁴ we can learn much to help us when dealing with civilian wounds.

Abdominal injuries can be roughly divided into two categories: those produced by blunt force and without penetration of the abdominal wall, and those produced by penetrating objects. Both types may be associated with other injuries, such as fractures, chest wounds, cranial wounds and trauma to the soft parts of the body. In the management of such casualties, one must be on the alert for multiple injuries and be ready to treat them in order of importance, or with two or three teams working at once on different regions. The need for early and adequate treatment of intra-abdominal injuries ranks second only to the control of severe hemorrhage.

Shock occurs following all forms of severe trauma. This condition is of varying degrees and usually appears early, but may occur after some hours have elapsed. Blalock⁵ classifies patients suffering from shock in two main groups: those who have bled from injured blood vessels and appear with cold extremities due to vasoconstriction, and those whose blood loss has occurred into the great veins of the body owing to vasodilatation and who may have warm extremities. Both types show restlessness, pallor, air hunger, thirst and lowered blood pressure. A rapid, thready pulse occurs in the first group. Shock is best treated by warmth, sedation with morphine and blood or plasma transfusions according to the extent of hemoconcentration. Massive hemorrhage is the only condition warranting immediate surgical intervention before shock has been effectively treated. In abdominal injuries, this preliminary condition must be handled with the greatest expedition since the time factor is of great importance.

Mulholland⁶ points out the cause of death in abdominal trauma. The mortality in a group of cases studied by him was 51 per cent. Of these victims, 43 per cent died of shock, 43 per cent of infection, and 13 per cent of hemorrhage. It appears that future efforts will do much to lower this rate, since both shock and infection are under better control than formerly. Heyd⁷ calls attention to the simple objective test of the operative state of a patient under these conditions: that is, the warmth of the body. Doubtless many cases are subjected to surgery before shock has been controlled.

NONPENETRATING WOUNDS

Nonpenetrating abdominal injuries may result from comparatively slight trauma, such as a fall while at play. Various gradations from this to very severe crushing injuries occur. A new type of injury produced by blast has appeared since civilian bombing has been recorded. This occurs when an explosion takes place in close proximity to the victim without any shell fragment's penetrating the body. Petechial hemorrhages have been described in the brain, lungs and abdominal viscera. Actual perforations of hollow viscera have been reported, as well as thromboses of large blood vessels supplying segments of intestine. Similar injuries have been reported to men in the water from nearby explosions in the sea.⁸ Most of the intra-abdominal lesions, however, are produced through considerable impact against the abdominal wall by flying or falling objects or by moving vehicles.

Fatheree⁹ has collected from the literature the fact that 60 to 78 per cent of intra-abdominal injuries by blunt force affect the solid organs. This is due to the firmer fixation of these structures as compared with the mobility of the hollow viscera. When one is confronted with the problem of intra-abdominal trauma, it is important to realize the possibility of serious injury and to classify each case as one of minor injury to the parenchymatous organs requiring no operation, a hopeless situation with multiple injuries beyond rescue, obvious injury to a hollow viscus or continued hemorrhage from solid organs or the mesentery, or a borderline case in which there is reason for doubt. Both the last-named types require surgery as soon as shock has been controlled and conditions permit. The sooner a rupture of the intestine or bladder is sutured, the greater is the likelihood of a successful outcome.

Liver injuries are of all gradations. The mild ones may be recognized by the minimal trauma and symptoms. If one could be sure that there were no other viscera involved, many exploratory

laparotomies could be avoided. Hinton¹⁰ pointed out years ago that the bleeding in liver injuries has usually ceased at the time of exploration. It has often been observed that it is unwise to disturb such a clot, and one should be content to remove the extravasated blood and bile from the abdominal cavity by means of a suction tip alone. In large rents that are still bleeding, one must either pack the area with gauze, cauterize the bleeding surfaces or attempt suture. Corriden¹¹ has reported a case of severe subcapsular rupture of the liver successfully treated by a large transplant of rectus muscle into the sulcus. Grey Turner¹² points out that the mortality in liver injury is high and states that hemorrhage accounts for 60 per cent and sepsis for 40 per cent of the deaths. He describes an ingenious method of suturing a rent in the liver. By first placing a large strand of catgut through the substance on each side of the opening parallel to the edges, he is able to prevent his deep transverse sutures, passed outside the transverse strands, from cutting out. Totten¹³ and Estes¹⁴ have called attention to digital compression of the hepatic artery and portal vein during the manipulations necessary for controlling the bleeding from the wound itself. Hawthorne, Oaks and Neese¹⁵ report an interesting case of liver injury manifesting itself by repeated massive hemorrhage through the bile ducts.

In a previous publication, I¹⁶ have cited a fatality from autotransfusion of the blood collected from the abdominal cavity in a patient with ruptured liver. This patient died of anuria, probably through the toxic action of the bile on the kidneys. Since this case was published in 1931, various authors have called attention to the danger of autotransfusion in liver injuries. The term "hepatorenal syndrome" has been used by Orr and Helwig.¹⁷ More recently McCorkle and Howard¹⁸ have reviewed the question of liver damage followed by other complications, and report a case showing transient urinary suppression following laparotomy for acute ruptured liver. The patient was not autotransfused and recovered. Associated low kidney function has long been recognized as a dangerous sequel to operations on patients with chronic liver disease. Coller, in his discussion of Orr and Helwig's paper, suggests that oliguria, under these circumstances, might be attributed to other physiologic alterations so often associated with poor liver function rather than to any specific toxin generated by the damaged liver.

The *spleen* is injured with considerable frequency. This condition may manifest itself by overwhelming shock, pain referred to the shoulder and extreme leukocytosis. On the other hand, many cases of delayed bleeding are reported.¹⁰⁻²²

An injured ballplayer, for instance, may even continue in the game for a while, or may not be suspected of a serious injury until exertion several days later produces a second burst of bleeding. McIndoe¹⁹ collected a total of 45 cases of bleeding delayed from two days to six months after the initial trauma. He classifies spleen injuries as follows: minor, superficial, capsular rupture or slight splenic contusion producing parenchymal ecchymosis; intrasplenic hematoma and subcapsular hemorrhage without capsular rupture; and capsular and parenchymal rupture with pericapsular hematoma. Rousselot²³ adds avulsion of the spleen from the hilus vessels. He calls attention to the over-all mortality of 30 per cent in injuries to the spleen, but in his group of 9 uncomplicated injuries, all the patients recovered. He made follow-up studies of these cases in order to determine that late secondary anemia does not occur following splenectomy. All authorities admit that splenectomy is the treatment of choice. Few advocate suture or tamponade. One known V-shaped rent in the spleen, discovered during laparotomy for a more severe injury, was left untreated and recovery took place.²⁴ Multiple complicating injuries and delayed improper treatment account for the high mortality.

Kidney injuries without penetration are of common occurrence. More of these of severe proportions have occurred since the high-speed automobile was developed. Authorities are somewhat divided regarding early surgery versus conservative measures. Nonoperative treatment certainly results in a successful outcome in the majority of kidney contusions. On the other hand, there are valid reasons for removing hematomas about the kidney.²⁵ All agree that one must determine the presence of a functioning kidney on the opposite side. Intravenous pyelography is the method of choice, although some authorities prefer retrograde pyelography, since this gives a better idea of the extent of the injury. Peacock²⁶ reports a fatal hemorrhage following retrograde pyelography for ruptured kidney. Robertson²⁷ and others stress conservative surgery when any is done. Turton²⁸ gives experimental data to support repair of the kidney. He also advises exploration through a loin incision except in cases with complicating intraperitoneal lesions. His dictum is, First, save the patient, then save the kidney. When the renal pedicle is torn, a rapidly developing mass in the flank will manifest itself; under these circumstances, nephrectomy is justifiable and usually necessary. Associated injuries to the descending colon require laparotomy. Cases demanding operation are naturally associated with a higher mortality than are those of less severe trauma.

The *pancreas* may be injured by blunt force, owing to its fixed position across the ridge of the spine. Few cases of successful immediate operation are reported. Cysts may form, which can later be removed or marsupialized.²⁹ Dixon³⁰ reports 2 cases of pancreatitis associated with rupture of the duodenum. There was no evidence of injury to the pancreas in either case. Both patients died and one was studied at autopsy. The condition cited implies a mystifying mechanism, since acute perforation of the duodenum from ulcer is rarely if ever associated with pancreatitis.

Hollow viscera, when ruptured, almost invariably result in death unless prompt action is taken to remedy the defect. The earlier operation can be undertaken, the better is the opportunity for a successful outcome. One must often explore the abdomen under these circumstances, to rule out a suspected perforation. There is little or no hazard from a negative exploration under modern conditions, and no apologies are needed for this procedure. It is not good judgment to delay exploration until the diagnosis can be confirmed by x-ray films that demonstrate free air in the peritoneal cavity, or to wait until the signs of peritonitis manifest themselves.

Whenever possible, rents in the stomach and intestine should be closed without resection. If the bowel has been stripped of its mesentery or the rent goes completely through the bowel into the mesentery, resection and anastomosis are justifiable. In colon wounds it is best to suture the opening if it is a small one and in a fixed portion of the bowel. If it is in the free mobile cecum or sigmoid, exteriorization is the method of choice. In perforations of the colon not exteriorized, a proximal vent should be established after suture. One must have in mind the possibility of traumatic thromboses of the large blood vessels, as such cases have been caused by blast injuries.² In the event of doubt concerning the viability of a segment of bowel, it is best to do a proximal complete colostomy.

It may be irrelevant to mention at this point injuries to the colon from compressed air. It seems, however, that this hazardous prank cannot be overemphasized. Brown and Dwinelle³¹ collected 60 such cases from the literature and added 3 of their own. It is interesting to note that as little as 4 pounds of pressure can cause rupture of the colon. The use of compressed-air hoses for dusting off workmen's clothing in industrial plants should be forbidden. The mortality in these injuries is 100 per cent without surgery and 42 per cent with it.

The *urinary bladder* may be ruptured by blunt force. Damage to this organ should be looked for in all traumas to the low abdomen. Injury

to the urethra and bladder are often associated with fractures of the pelvic bones. The simplest method of diagnosis is to catheterize the patient, if he cannot void. A large amount of bloody urine indicates a kidney lesion. Absence of urine or a few drops of bloody urine indicate bladder injury. Weyrauch and Peterfy³² have shown that cystometrograms are unreliable as a means of diagnosing a ruptured bladder. Peacock³³ reports 28 cases with only 4 deaths. Eighty-five per cent of his cases were associated with fracture of the pelvis. Early recognition and early operation were responsible for his good results.

PENETRATING WOUNDS

Penetrating wounds of the abdomen require less diagnostic acumen than nonpenetrating ones. If a large vessel is severed, death ensues so rapidly that the patient does not live to reach the surgeon. Thus, patients with lateral anteroposterior wounds are the ones he generally sees, whereas those with wounds in the midline seldom come to him before death. Gordon-Taylor^{3, 34, 35} points out that wounds penetrating the abdomen from one side to the other are more serious than those proceeding anteroposteriorly. Also, he calls attention to the combination of abdominal and chest wounds. Apparently, the left hypochondrium is more vulnerable than any other quadrant. Thoracic surgeons have developed the chest approach to this region—many of them prefer to attack the spleen and the upper end of the stomach by this route. Multiple injuries are as a rule more dangerous than single wounds; much depends, however, on the extent of the injury. The degree of hemorrhage is, according to Storck,³⁶ the most important factor in success or failure.

One should make a definite study of the course of the projectile. If there is only a wound of entry, a single film will locate the foreign body. It is not essential to remove it in all cases, but one should know in what region it lies. This gives the best clue concerning the organs most probably injured. Great stress is placed on buttock wounds, since they so often range upward. The fragment of shell casing or bullet may well lodge in the urethra or bladder, penetrate the rectum or traverse the abdomen. The most serious of all omissions is to overlook an injury to the colon, since recovery is extremely rare if perforation of this viscus is not recognized and properly treated.

In penetrating injuries of the abdomen, regardless of the direction of the projectile or its size, one must at the earliest possible moment determine by operation the extent of the injury and do the logical repair of the wounded parts. If there turns out to be only a superficial tract, traversing portions

of the abdominal wall, so much the better. Perforations of the stomach must be expected to have a wound of exit on the posterior wall. One should approach the deeper wound by dividing the gastrosolic omentum or by anterior gastrotomy. Wounds of the duodenum may involve both walls. Fraser²¹ cites a case of complete severance of the duodenum treated successfully by turning in both ends and doing a posterior gastrojejunostomy. Perforations of the small intestine should be sutured without resection wherever possible. The mortality is lower in wounds of the jejunum than in those of the ileum.³⁷ After operations on the small intestine for traumatic wounds, one should employ Wangenstein suction or, if possible, suction drainage by a Miller-Abbott tube or some modification of it.

The colon presents a more serious problem; many of the pertinent points regarding this structure have already been made in the section on nonpenetrating wounds. Ogilvie,³⁸ of the British Army, emphasizes the importance of exteriorization when possible and proximal colostomy if suture is accomplished. These are good general surgical principles and should be rigidly observed. Drainage to the site of injury is advocated, care being used to keep the end of the drain away from the suture line.

Chemotherapy is rapidly becoming standardized. The tendency to apply the sulfonamide drugs locally is now being seriously questioned. Kennedy³⁹ states that all combatants are furnished with some form of these drugs, to be taken by mouth, if possible, as soon as a wound is received. Doubtless it will be possible to give many of the injured sulfadiazine by the intravenous route at an early hour. This method was found of inestimable value in treating a large series of severe burns in a recent civilian catastrophe.⁴⁰ It seems probable that the local use of the drug will be reserved for emergency dressings or for its bacteriostatic effect in the treatment of contaminated wounds. The sulfadiazine level in the blister fluid of a burn is comparable to that in the blood stream.⁴¹ There is a widespread use of sulfanilamide powder intraperitoneally following any gastric or intestinal operation. There is a rapid absorption of this drug through the portal system. Lyons⁴² has pointed out that this may, under certain circumstances, be very dangerous to the liver. The greatest of all sins is to depend on this drug to offset faulty technic.

It appears that the secondarily invading or late developing staphylococcus, responsible for so many deaths and such prolonged sepsis and disability, may be curtailed or even eliminated by the use of penicillin.

Anesthesia in abdominal trauma is a controversial subject. Local anesthesia is advocated by very few. Spinal anesthesia is preferred by Storck⁴³ and Bove,⁴³ and Pentothal Sodium intravenously by Ross and Hulbert⁴⁴; the latter was also found useful by Moorhead⁴⁵ at Pearl Harbor. Strode⁴⁶ and many others conclude that ether is after all the safest and easiest anesthetic for most abdominal wounds.

Wound preparation has been dealt with by Reid and Carter,⁴⁷ Koch⁴⁸ and Kerrigan.⁴⁹ It is obvious that chemicals are of secondary consideration. Careful mechanical cleansing by neutral soap and water with cotton pledgets for ten minutes under sterile precautions obviates the use of antiseptics. The traumatic wound must be kept covered and the washing done away from, rather than toward, it. After this is done, the wound itself is irrigated with warm physiologic saline solution. Reid and Carter prefer to omit the wound irrigation. This is doubtless good advice to those who understand proper wound excision.

First-aid treatment of wounds of the abdomen should consist in the application of a sterile dressing only; this should be held in place by a suitable binder and not be removed until the patient is ready for the operating room. Too much stress cannot be laid on the possible contamination of wounds by ungloved and unmasked personnel prior to definitive treatment.

Ogilvie³⁸ has called attention to too wide an excision of skin. He says, "Skin is viable after trauma, resistant to infection and irreplaceable—no more must be removed than the bruised edge, that is, one-eighth inch at the most." He further points out that patients with abdominal wounds should not be transported early after operation, but should be allowed to recover from it before being moved any distance. Caution is given concerning the primary suture of traumatic wounds, since too many of them become septic. Delayed closure is advocated. It is important not to pack the wounds too tightly with vaseline gauze, and dressings must be made tight for transportation purposes. Plaster of Paris reinforcement during transportation has been found useful.

Tetanus antitoxin and gas-bacillus antiserum should be used following all civil wounds; the former can be omitted if it can be ascertained that the victim has previously been immunized with tetanus toxoid, but a "booster" injection of toxoid should be administered.

CASE 29041

PRESENTATION OF CASE

A seventy-one-year-old insurance broker entered the hospital because of inability to swallow solids or liquid food.

Three months prior to admission he gradually became unable to swallow solid food, choking whenever he attempted to ingest anything other than fluids. He then developed a similar trouble in swallowing liquids. Whenever he drank liquids he complained of pain and burning in the throat. The patient attributed his trouble to infected teeth, which were extracted on the day prior to admission. During his illness he lost approximately 40 pounds.

The family and past histories were noncontributory.

Physical examination revealed a markedly emaciated, weak, pale man who was having considerable difficulty because he seemed to be choking on mucus collected in the mouth and throat. At times he seemed slightly confused. The skin was thin, white and atrophic. The pupils were equal, round and reacted to light. There was a slight nystagmus on extreme deviation to the right or left, and a senile ectopion. The patient was edentulous, but there were several draining tooth sockets. The tongue was red, smooth and fissured. The pharynx was congested. Skin fissures were prominent at the angles of the mouth. The trachea was in the midline. Expansion of the chest was fair. There was impairment in resonance at the left apex anteriorly, and breath sounds were slightly suppressed at the right base posteriorly. No rales were audible. Cardiac dullness was percussed 8 cm. to the left of the midsternal line in the fifth intercostal space. The cardiac rhythm was totally irregular, but no pulse deficit was noted. A systolic murmur was audible at the apex. The abdomen was held tense, and there was a questionable generalized abdominal tenderness. There was pitting edema of the legs, feet and sacrum.

The blood pressure was 155 systolic, 60 diastolic. The temperature was 100°F., the pulse 68, and the respirations 20.

Examination of the blood revealed a hemoglobin of 8.9 gm. per cent, a red-cell count of 2,970,000

and a white-cell count of 11,200, with 47 per cent polymorphonuclear leukocytes, 7 per cent large lymphocytes, 29 per cent small lymphocytes, 14 per cent monocytes, 2 per cent unclassified cells and 1 per cent nucleated red cells. In the smear, there was a moderate variation in the size of the red cells; many were larger than normal, and rare microcytes were present. There was a moderate achromia, and the platelets were decreased slightly.

On the second day a barium meal was attempted. On fluoroscopic examination of the esophagus, the pharyngeal muscles appeared to be paralyzed. There was pooling of the barium in the hypopharynx, and the barium passed upward into the nasopharynx. The cervical esophagus was narrowed, and it was difficult to visualize this area because of the patient's weakness and the small amount of barium that passed through this area of narrowing. There was evidence of pressure on the esophagus by the thyroid gland at the level of the sternoclavicular joint, and the esophagus was displaced to the right. A small amount of barium spilled over into the bronchial tree.

When the patient returned from the X-ray Department he seemed to be choked up with barium. Suction was instituted, but he died approximately half an hour later.

DIFFERENTIAL DIAGNOSIS

DR. JACOB LERMAN: There is no statement about orthopnea or distention of the neck veins. The trachea was in the midline, and there were no palpable lymph nodes. The thyroid gland was not felt. Was the patient resting quietly lying down, or was he propped up in bed?

DR. TRACY B. MALLORY: There is no statement regarding orthopnea.

DR. LAURENCE L. ROBBINS: I did the fluoroscopy. The patient was not in particularly good condition, but so far as I could determine in the dark room he seemed like a good many patients who have considerable difficulty in breathing and swallowing at the time of examination. His condition did not seem particularly alarming; however, we did not give a great deal of barium. With the first mouthful of barium it was noted that there was widening of the hypopharynx and that the pyriform sinuses were completely filled. A small amount of barium spilled into the esophagus, but it seemed to be more from gravity than from muscular action; it was seen that the cervical esophagus was somewhat narrow. Whether there was actual intrinsic tumor there, I could not be positive, but on the spot films the mucosa looks pretty good. There is evidence of narrowing of the esophagus at the level of the sternoclavicular joint, and it is displaced considerably to the right side. On

this film you can see that the barium has spilled back into the nasopharynx, which is good evidence of paralysis of the pharyngeal and palate muscles.

DR. LERMAN: What about the trachea?

DR. ROBBINS: It is normal so far as I can see.

DR. LERMAN: Why did you say the thyroid gland was the cause of pressure?

DR. ROBBINS: Because of the location of the lesion. I cannot be sure, however, that it was not something else. On this film you can see flecks of barium that are in the right main bronchus, and some of them are even as low as the right-lower-lobe bronchus.

DR. LERMAN: We have a markedly emaciated old man who had considerable difficulty in swallowing, an obvious nutritional deficiency, a moderate anemia of the normochromic, slightly macrocytic type and x-ray evidence of pressure on the esophagus, with displacement toward the right. From the story I gather that the deficiency syndrome antedated the dysphagia. It is difficult for me to be certain of that. Could he have had deficiency of this degree after only three months of esophageal obstruction?

Let us consider the thyroid gland as the cause of his trouble. It is hard to believe that any thyroid tumor could compress the esophagus and displace it to this degree without involving the trachea. Certainly thyroid malignancy that could obstruct the esophagus almost completely would do so only terminally, at least according to my experience. Chronic thyroiditis can obstruct the esophagus by posterior extension of the process, but I do not see how it can displace the esophagus. Moreover, I have never seen chronic thyroiditis produce almost complete obstruction. A toxic nodular goiter that is substernal, such as this would have to have been, should be considered. It would at least explain the relatively rapid development of the deficiency syndrome. In cases of thyroid disease, if there is clinical evidence of one or another deficiency syndrome, one must suspect associated hyperthyroidism. I have seen several thyrotoxic patients with peripheral neuritis and other evidence of vitamin B deficiency. At the present time I have under my care a patient with hyperthyroidism and marked dysphagia, associated with glossitis and pharyngitis of the type seen in vitamin B deficiency, whose basal metabolic rate is $+55$ per cent. She has been on a poor diet because of anorexia more than anything else. I cannot imagine a thyroid nodule that could produce this much pressure on the esophagus without producing pressure on the trachea and other evidence of pressure in the superior mediastinum. Obviously there were no symptoms of hyperthyroidism. Therefore it seems to me that we have to discard toxic goiter

as a cause of the esophageal obstruction. On the other hand there should have been found at autopsy an ordinary nontoxic nodule, which was independent of the main cause of death.

Lymphoma has to be considered, but there is nothing specific in the record to lead to this diagnosis.

I shall now consider two diseases. Generalized deficiency, no matter how it develops, may produce the picture of Plummer-Vinson syndrome, which this patient may have had. However, it is usually associated with hypochromic anemia. I believe that Plummer-Vinson's disease is part of a vitamin B deficiency syndrome, and that this case represents one type. Many of these patients with deficiency are prone to develop malignancy of the mucosa—mouth, pharynx or esophagus. Consequently it is likely that there is malignancy in the upper part of the esophagus in this case. One can reason the other way around: he had esophageal malignancy to start with and the interference with swallowing of food caused development of the deficiency state. Against this course is the relatively short duration of the obstructive symptoms.

In addition, there is the cardiac picture, which was probably due to arteriosclerotic heart disease with auricular fibrillation and, possibly, congestive failure. Other than peripheral edema, there was no evidence of congestive failure. One might therefore suspect that the edema was due to deficiency disease (nutritional edema) and not to congestive failure. Thus I am left with the following diagnoses: carcinoma of the esophagus and nutritional deficiency, with an independent, nontoxic, nodular substernal goiter, and arteriosclerotic heart disease.

DR. FULLER ALBRIGHT: Is it unusual to have the esophagus displaced by carcinoma?

DR. LERMAN: It depends on where the tumor arises. Most malignancies of the thyroid are asymmetrical.

DR. ALBRIGHT: It would constrict it down but would not displace it?

DR. LERMAN: I cannot answer that.

DR. MALLORY: I can imagine displacement, Dr. Albright, especially if the tumor extended into the deep cervical nodes on one side of the neck more extensively than on the other.

DR. EDWARD B. BENEDICT: This is not the usual picture of carcinoma of the esophagus. To have paralysis of the muscles of the pharynx is not usual either; I have never seen that except in myasthenia gravis.

DR. ROBBINS: It is occasionally attributed to pseudobulbar paralysis. This looks a good deal like the hypopharynx in myasthenia gravis except

that one sees only weakness whereas this looks like nearly complete paralysis.

DR. BENEDICT: You said you thought the mucosa was normal.

DR. ROBBINS: So far as I could tell.

DR. BENEDICT: That would certainly be against carcinoma of the esophagus, if intrinsic, as well as against myasthenia.

DR. J. H. MEANS: How is myasthenia going to push the esophagus to one side?

DR. BENEDICT: That would not do it alone.

DR. ROBBINS: I do not believe that the location of the lesion had anything to do with the paralysis of the pharyngeal muscles, because the mass is too far away from the point where paralysis is most noticeable.

DR. MEANS: That paralysis bothered me no end. I do not see how you can hook it up with the same trouble from the diagnostic point of view.

DR. MALLORY: I might just as well confess that we are not going to explain the paralysis.

CLINICAL DIAGNOSIS

Carcinoma of esophagus.

DR. LERMAN'S DIAGNOSES

Carcinoma of esophagus.

Nutritional deficiency.

Nontoxic nodular goiter (substernal).

Arteriosclerotic heart disease.

ANATOMICAL DIAGNOSES

Substernal colloid goiter.

Benign ulcer of esophagus.

Arteriosclerosis, moderate: aortic, coronary and cerebral.

Pulmonary emphysema.

Emaciation.

PATHOLOGICAL DISCUSSION

DR. MALLORY: This man had a very large substernal goiter, weighing 350 gm., which clearly was the cause of the displacement of the esophagus. He also had a benign ulcer of the esophagus at a much higher level; it was only 2.5 cm. below the epiglottis, too high to be in any way connected with the thyroid tumor itself. We have no explanation, as I said, for the pharyngeal paralysis. The possibility of peripheral neuritis did not occur to us and was not called to our attention at the time of autopsy. We did go through the cerebrum and medulla with some care, and there was no medullary lesion to account for the paralysis. I cannot eliminate the possibility of peripheral paralysis, although we have no evidence that other peripheral nerves were involved.

DR. LERMAN: The Plummer-Vinson syndrome has been described several times in association with paralysis of the pharynx. That is why I attributed the paralysis to the deficiency state.

DR. BENEDICT: What was the cause of death?

DR. MALLORY: There was extensive emphysema. There was mild coronary sclerosis without occlusion, and marked emaciation, which was noted clinically; we found nothing else.

DR. BENEDICT: He apparently did not inhale much barium.

DR. MALLORY: Traces of barium were found down to the end of the bronchial tree. On the other hand as much and more lipiodol is frequently instilled without any respiratory embarrassment. I am sure that the patient did not die of bronchial obstruction.

DR. ROBBINS: Many of the patients who have paralysis of the hypopharynx spill barium into the trachea in larger amounts than this man did without any sequelae.

CASE 29042

PRESENTATION OF CASE

A sixty-six-year-old plumber entered the hospital because of shortness of breath.

For many years he had had a chronic hacking cough that occasionally was productive of small amounts of sputum. Six months before entry, he had to give up working because of generalized weakness, and four months later he became short of breath after only moderate exertion. The dyspnea became progressively worse, and he became orthopneic. Four weeks before entry his cough increased and he raised several teaspoonfuls of sputum, which was pink stained at times. During the month prior to admission his arms, neck and jaws became swollen, particularly after lying down, and veins appeared over his chest. At no time did his ankles swell. His appetite was unchanged, and his weight had been maintained at 137 pounds.

The family history was noncontributory. Fourteen years before entry he was found to have a systolic blood pressure above 200. He never noted any frequency, urgency, hematuria, pyuria, nocturia, dysuria, costovertebral-angle tenderness or headache.

Physical examination revealed a well-developed man who was obviously dyspneic and orthopneic. There was a striking pitting edema of the upper extremities, and engorgement of the veins of the upper extremities and neck. There were many dilated veins over the chest to the level of the costal margins. There was slight cyanosis of the

lips. Many small matted lymph nodes were felt in the left supraclavicular fossa and left axilla. The trachea was deviated to the right. Over the right lung anteriorly and posteriorly there were greatly diminished breath sounds. There was no change in the transmission of fremitus or spoken voice. There was dullness at the right lung base posteriorly, and diaphragmatic excursions could not be demonstrated on that side. The cardiac dullness was percussed 7.5 cm. to the left of the midsternal line. The heart sounds were of good quality, and no murmurs were audible. The liver was percussed 5 cm. below the costal margin. The spleen was not felt. There was no edema of the lower extremities.

The blood pressure was 210 systolic, and 100 diastolic. The temperature was 98.8°F., the pulse 80, and the respirations 20.

Examination of the blood revealed a hemoglobin of 10.2 gm., a red-cell count of 3,200,000, and a white-cell count of 14,100, with 83 per cent polymorphonuclear leukocytes, 7 per cent large lymphocytes, 3 per cent small lymphocytes, 3 per cent monocytes, and 4 per cent myelocytes; there was a slight anisocytosis of the red cells. The urine was acid, had a specific gravity of 1.018, gave a ++ test for albumin, and contained numerous hyaline and finely granular casts. The Sulkowitch test for urinary calcium was ++. The blood non-protein nitrogen was 28 mg. per 100 cc.; the bicarbonate was 25.3 milliequiv., and the chloride 86.4 milliequiv. per liter.

A chest roentgenogram demonstrated a lobulated mass in the right upper mediastinum apparently arising from the tracheobronchial angle, with several smaller masses lateral to it. The heart was slightly displaced to the right and was slightly enlarged. The diaphragm was low on both sides, the right half showing impaired motion. The right lower lobe of the lung was decreased in size, as visible in the lateral view, and contained flecky areas of increased density. The soft tissues of the neck were enlarged, particularly on the right, and there were several areas of calcification on both sides. Venous-pressure studies were done with the patient sitting at a 60° angle with the bed. The pressure in the right antecubital vein, held at the level of the second costochondral junction, varied from 400 to 410 mm. of water (normal, 40-110 mm.) in three determinations, and showed a good pulse excursion. The simultaneous pressure in a vein over the internal malleolus was 100 mm. A biopsy specimen obtained from the left axilla showed only chronic inflammation. A bronchoscopy was suggested, but it was thought that the patient was too sick to withstand the procedure.

On the eighth day 150 r of x-ray therapy was given to the mediastinal mass. That afternoon he was found to be unresponsive. The entire body was flaccid. The pulse was 90, and the respirations 20. He was in an oxygen tent at that time. Two hours later he died. Terminally the respirations varied between 35 and 25.

DIFFERENTIAL DIAGNOSIS

DR. AUSTIN BRUES: May we see the x-ray films?

DR. LAURENCE L. ROBBINS: This is the lobulated mass that was described, with these other areas of density lateral to it; I note that the right lower lung field is less bright than the left. In the lateral view you can see that there are small areas of increased density posteriorly, so that the pulmonary lesion must be located in the lower lobe. The areas of calcification that were described in the neck are these. I think the diaphragm is low on the left, but that does not agree with the record, which states it was low on both sides.

DR. BRUES: It is helpful to have the right side high as well as paralyzed.

That is not a filling defect in the stomach, is it?

DR. ROBBINS: No; I do not believe so.

DR. BRUES: The differential diagnosis is that of upper mediastinal obstruction with compression of the vena cava, presumably including or below the azygos vein because of the venous distention and massive edema. Aside from that we have nothing but an enlarged liver and hypertensive renal disease, to which I shall refer only in the final diagnosis. Mediastinal compression can be due to tumor, benign or malignant,—infection or aneurysm. Taking up the possibilities, carcinoma of the lung, arising in the tracheobronchial angle, with metastases to the bronchial nodes would account for the greater part of the picture. I think the lesion and metastases were suitably located for this. We should have to include a lesion below, either a metastasis or a plugged bronchus, to account for atelectasis in that region—I take it that the lower lobe was atelectatic. Against the diagnosis of carcinoma of the lung we should consider the long history of cough. The history does not say for exactly how many years he had been coughing. It says "many years." I believe if that meant a year and a half or two years it would be consistent with cancer. Otherwise, we have to assume he was coughing for some other reason before the present illness. With calcification in the neck he probably at one time had tuberculosis of the cervical nodes, but we have no evidence of old pulmonary tuberculosis. The absence of weight loss is against carcinoma, but weight loss is certainly not always found in cancer. Hemoptysis is one of the early

symptoms indicating erosion of the bronchus and is therefore in favor of cancer.

This exact picture may also be produced by tuberculosis of the bronchial nodes; chronic tuberculosis of the mediastinum is common in children but extremely uncommon in adults, and therefore is very improbable. As for Hodgkin's disease, lymphosarcoma or leukemia, hemoptysis is not usually an accompaniment of these conditions. The localization of the mediastinal involvement to the upper mediastinum is somewhat more characteristic of carcinoma. Certainly, I should say that lymphoma or some other radiosensitive tumor is by no means out of the question. It is my second best diagnosis, and I think it was perfectly correct that radiotherapy in lymphoma doses was given; this should always be done in such a case if the diagnosis cannot be settled.

We must include in the differential diagnosis of mediastinal tumors, such conditions as benign tumors, teratomas and localized infections. These would be expected to displace things away from the lesion because they grow by expansion rather than by infiltration. We might consider aneurysm, but there is nothing to suggest it. There is no serologic report, but I should not go all out in favor of aneurysm even if the Hinton test were positive.

As for metastatic malignancy—it is anybody's guess where the malignancy might be. Perhaps an intra-abdominal tumor would be most likely to do this. If this is carcinoma of the lung, which I think on the basis of the whole picture is the best available diagnosis, there are metastases to the bronchial nodes. Most statistics show that the majority of carcinomas of the lung metastasize to the regional nodes and that the next commonest site is the liver. With an enlarged liver, we might therefore assume it to be involved. What about involvement of the adrenal glands? The chloride was low (86.4 milliequiv.), the blood having presumably been taken from the antecubital vein in the edematous area. There was obvious venous stasis. Under these circumstances one would expect the chloride to be low because of selective diffusion out of the bloodstream into the swollen interstitial space. I am not going to believe that the chemical findings indicate anything else, although bilateral adrenal metastases are frequently seen in cancer of the lung.

My diagnosis therefore is carcinoma of the lung arising in the right bronchus, with metastases to the bronchial nodes, and involving the vena cava and azygos vein by pressure or thrombosis and probably the phrenic nerve, since the paralyzed diaphragm is high and not low. I should say that there was partial atelectasis of the lower lobe due

to bronchial obstruction or compression from metastases, metastases to the liver but probably not to the adrenal glands; hypertensive heart disease, with slight vascular changes in the kidneys; and, finally, old tuberculous infection in the cervical nodes.

DR. J. H. MEANS: I saw this man just before he died. I was not confident that he had lymphoma, but thought he was entitled to treatment. However, there was evidence of such severe mediastinal pressure that we debated about giving it because of the question of acutely increasing the pressure and perhaps killing him. But finally, after consultation with the X-ray Department, it was decided to give a small dose. I talked it over with the Surgical Service and raised the question of whether splitting the sternum would offer a feasible method of relieving the upper mediastinal pressure, but they did not believe it advisable.

DR. JACOB LERMAN: When this patient first came in, without having seen the x-ray films but knowing that he had lymph nodes in the axilla and one very large one in the sternoclavicular region, I believed that he had lymphoma. After the x-ray examination the tendency was to swing away from this diagnosis toward carcinoma, either in the mediastinum or in the bronchus.

DR. RULON W. RAWSON: I saw this patient in the Out Patient Department. At that time he presented no lymph nodes, and we did not consider the diagnosis of lymphoma. The spleen was enlarged, and I was able to demonstrate that the liver was also enlarged.

CLINICAL DIAGNOSIS

Superior mediastinal tumor (? lymphoma or carcinoma).

DR. BRUES'S DIAGNOSES

Carcinoma of right upper bronchus, with metastases to bronchial nodes and liver.

Secondary compression or thrombosis of superior vena cava.

Atelectasis, right lower lobe.

Hypertensive heart disease, with slight renal vascular changes.

Old tuberculosis of cervical nodes.

ANATOMICAL DIAGNOSES

Bronchiogenic carcinoma, oat-cell type, with extension to mediastinum and lower cervical region.

Invasion of superior vena cava.

Obstruction of thoracic inlet.

Cardiac hypertrophy.

Nephrosclerosis.

Arteriosclerosis: coronary and aortic.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The autopsy showed a large tumor mass in the upper mediastinum, which encircled the trachea and great vessels. The mass was rather soft and on section was pink and shiny, suggesting sarcoma. However, a quite unusual finding was that the tumor had grown directly through the wall of the superior cava; tumor nodules were even present within the cava itself (actual invasion of the vessel wall by lymphoma is quite unusual). On opening the trachea a number of raised submucosal nodules were felt, and when the right bronchus wall was opened, a mucosal tumor appeared. On the basis that the mucosa of the bronchus was involved and the wall of the vena cava was eroded, we thought at the time of autopsy that cancer was more likely than lymphoma. When the histologic sections came through, the mass turned out to be an undifferentiated small-cell tumor, the cells of which were oval to slightly spindle shaped, so I am quite confident that it was an oat-cell carcinoma of the lung, not lymphoma. We found no distant metastases. There was a small nodule in the adrenal gland, but that turned out to be a cortical adenoma, so that the patient had an excessive rather than a diminished amount of cortical tissue. The liver and spleen were not involved. The deeper nodes of the neck did contain tumor similar to that in the mediastinum. There was also a mass of tumor tissue at the apex of the right lung, which formed sort of a pleural cap over the apex. He had severe emphysema, and I think that his many years of cough were based on that. There was some pulmonary fibrosis, also aspiration of blood into the right lower lobe, which I believe accounts for the density observed by the radiologist in that area.

The kidneys showed mild vascular changes, and

the heart was moderately hypertrophied, consistent with some years of hypertension.

DR. ROBBINS: Was the tumor of sufficient size to cause obstruction of the right main bronchus?

DR. MALLORY: A very small degree of obstruction only, I should think; there was nothing in the right lower bronchus to produce collapse specifically of the lower lobe as against the upper lobe.

DR. EDWARD B. BENEDICT: Is not bronchiogenic cancer an extremely rare cause of the upper-mediastinum syndrome?

DR. MALLORY: Yes, but we have seen it.

DR. BENEDICT: Is it not commoner in lymphoma?

DR. MALLORY: Yes, I think so, although of all mediastinal masses, bronchiogenic carcinoma is the likeliest to extend.

DR. MEANS: I should have thought carcinoma more likely to produce such a picture. It encircles the great vessels and squeezes them, whereas lymphoma presses on them.

DR. MALLORY: Lymphoma often invades the mediastinum diffusely. It rarely occludes the arteries, but it closes the veins by external pressure.

DR. RAWSON: But you would not expect lymphoma to invade the vessel wall?

DR. MALLORY: No; it certainly is uncommon.

DR. ROBBINS: What did you conclude regarding the immediate cause of death? I am interested because he had the radiation shortly before death.

DR. MALLORY: I think death was due to mediastinal compression, and I do not believe that the radiation made any difference—the patient would have died in approximately the same length of time regardless.

DR. ROBBINS: I wondered because of the amount of radiation he had. It was a fairly small amount and not sufficient to cause much swelling of the tumor, particularly in that length of time.

NATIONAL SOCIAL HYGIENE DAY

NATIONAL Social Hygiene Day, to be observed this year on February 3, is dedicated to the program for the prevention and cure of venereal disease. Starting with the premise that gonorrhea and syphilis can be prevented and cured, we may well ask ourselves, What has been learned of this prophylaxis and therapy and how may we best utilize our present knowledge?

Adequate education of the layman and the physician must be assured by placing the proper teaching material in the hands of every person competent to use it. Syphilis and gonorrhea must be detected early and treated promptly and prostitution must be suppressed, for the greater the delay the more serious are the complications and the longer the time required for cure. So also must all contacts be sought out and treated and the transmission of

disease to future generations must be prevented by premarital examination. Findings from such investigations should be repeatedly confirmed during the early months of pregnancy. Finally, citizens, both physicians and laymen, must co operate in all phases of this effort.

No magic formulas or secret weapons have been developed, but great advances have been made and are still being made in the treatment of these diseases. The general program of this attack is outlined in the pamphlet "Social Hygiene Takes Battle Stations" issued by the American Social Hygiene Association.

Such a program should be active in every state of the Union. In this connection it is of considerable satisfaction to learn that it is being carried out in far distant Hawaii* where the venereal disease rate in the armed forces is lower than the average in the Army as a whole. This territory is one of the safest places in the Union from the standpoint of venereal disease among the army personnel. If Hawaii can accomplish this, all other parts of the country can and should do so, especially when we realize how normal living conditions have been disrupted there. The Health Department of Hawaii is to be congratulated on performing a task which Surgeon General Parran has outlined so well as follows: "The conquest of syphilis and gonorrhea is not a task for official health agencies alone, nor yet for physicians alone, but is still a task for the whole people. By the union of public and private efforts we can minimize syphilis and gonorrhea and the ill health, suffering and waste they cause."

*Allison S. D. Facing the facts about venereal disease. *Health* 39 1942.

EFFECT OF WARTIME FOOD ON CHILDREN IN GREAT BRITAIN

THE *Lancet*,¹ editorially, admits that there is as yet little information about child health during the war, and that many factors other than diet may be effective. Thus, it is known that war has resulted in an increased carbohydrate intake for all ages and classes, on account of the shortage of meat, fish,

eggs, milk and fruit, and in a leveling of the diet, since rationing and lack of mass unemployment have brought about a fairer distribution of food-stuffs. The diet of the majority has been impaired, and the diet of the poorest has been improved.

The figures that are available show a definite reduction in the average weight increase in 1940 and 1941 as compared with that in 1936-1939, a rise in infant mortality amounting to 6.5 per thousand live births, and an alarming increase in deaths from tuberculosis. Among children under ten years of age, the deaths from all forms of tuberculosis in 1941 exceeded those of 1939 by 45 per cent, and in children under five, the deaths from tuberculosis of the respiratory tract had nearly doubled. A survey,² published in the same issue of the *Lancet*, shows a definite drop, although to no serious degree, in the average hemoglobin level compared with that in prewar groups of school children, and a high incidence of anemia among infants under two years of age. It is admitted that the vitamin C intake is below the optimum, but there is no evidence that this deficiency has retarded the growth or affected the health of British children; doubt has also been cast on the adequacy of the official dosage of "cod-liver oil compound" recommended for infants under six months of age, although no figures exist concerning the incidence of rickets for the winter 1941-1942. Certainly, careful and continued studies are indicated.

On the whole, the diet is considered to be reasonably adequate, although necessarily far from perfect, and is improving; in sharp contrast is the lot of millions of children on the Continent, as observed by Dr. W. D. Robinson in Madrid and by Dr. Harold C. Stuart in unoccupied France and reported by Dr. Stuart³ to the Suffolk District Medical Society in October. There, with blood ascorbic acid levels invariably zero and low vitamin A levels, many early manifestations of deficiency syndromes were found, and the more recent reports indicate the appearance of even severer deficiencies.

A world on short rations requires very serious contemplation of its nutritional problems.

MEDICAL EPONYM

GRAHAM STEELL MURMUR

This was described by Graham Steell (b. 1851) assistant physician to the Manchester Royal Infirmary, in the *Medical Chronicle* (Manchester) (9: 182-188, 1888) under the title, "The Murmur of High-Pressure in the Pulmonary Artery."

I wish to plead for the admission among the recognised auscultatory signs of disease of a murmur due to pulmonary regurgitation, occurring independently of disease or deformity of the valves, and as the result of long-continued excess of blood pressure in the pulmonary artery.

In cases of mitral obstruction there is occasionally heard over the pulmonary area (the sternal extremity of the third left costal cartilage), and below this region, for the distance of an inch or two along the left border of the sternum, and rarely over the lowest part of the bone itself, a soft blowing diastolic murmur immediately following, or, more exactly, running off from the accentuated second sound, while the usual indications of aortic regurgitation afforded by the pulse and so forth are absent. The maximum intensity of the murmur may be regarded as situated at the sternal end of the third and fourth intercostal spaces. When the second sound is reduplicated, the murmur proceeds from its latter part. That such a murmur as I have described does exist, there can, I think, be no doubt.

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON LEGISLATION

Attention of the members of the Massachusetts Medical Society is invited to the following bills which are of interest to the medical profession and are at present before the Legislature.

HOUSE 437. AN ACT REPEALING THE PROVISIONS OF LAW REQUIRING PRE-MARITAL SEROLOGICAL TESTS.

Section 1. Section twenty B of chapter two hundred and seven of the General Laws, inserted by section one of chapter six hundred and one of the acts of nineteen hundred and forty-one and as most recently amended by section two of chapter six hundred and ninety-seven of the acts of nineteen hundred and forty-one, is hereby repealed.

Section 2. Section twenty-eight of said chapter two hundred and seven, as amended by section two of said chapter six hundred and one, is hereby further amended by striking out, in the third and fourth lines and in the thirteenth line the words "sixty days" and inserting in place thereof, in each instance, the words:—six months,—so as to read as follows:—

Section 28. On or after the fifth day from the filing of notice of intention of marriage, except as otherwise provided, but not in any event later than six months after

such filing, the clerk or registrar shall deliver to the parties a certificate signed by him, specifying the date when notice was filed with him and all facts relative to the marriage which are required by law to be ascertained and recorded, except those relative to the person by whom the marriage is to be solemnized. Such certificate shall be delivered to the minister or magistrate before whom the marriage is to be contracted, before he proceeds to solemnize the same. If such certificate is not sooner used, it shall be returned to the office issuing it within six months after the date when notice of intention of marriage was filed.

Section 3. Section fifty-seven of said chapter two hundred and seven, as amended by section three of said chapter six hundred and one, is hereby further amended by striking out, in the second and in the fifth and sixth lines, the words "sixty days" and inserting in place thereof, in each instance, the words:—six months,—so as to read as follows:—

Section 57. Whoever performs a ceremony of marriage upon a certificate more than six months after the filing of the notice of intention of marriage as set forth in such certificate and not having used it fails to return it within six months after such filing, to the office issuing the same, shall be punished by a fine of not more than ten dollars.

HOUSE 79. Bill providing for the inspection of colleges, universities and medical schools approved for the purposes of medical education and for withdrawal of such approval in certain cases.

This bill was referred to the Committee on Public Health.

HOUSE 80. Bill relative to examination for registration as qualified physicians.

This bill was referred to the Committee on Public Health.

HOUSE 81. Bill relative to the scope of examinations for registration as qualified physicians.

This bill was referred to the Committee on Public Health.

HOUSE 89. Bill relative to certain clinics conducted by the licensed hospitals.

This bill was referred to the Committee on Public Health.

HOUSE 98. Bill relative to payment of medical, hospital and other services to old-age assistance recipients.

This bill was referred to the Committee on Pensions.

HOUSE 252. Bill further regulating medical services rendered under the workmen's compensation law.

This bill was referred to the Committee on Labor and Industries; the hearing will be held on February 2.

HOUSE 352. Bill relative to payment of medical, hospital and other services to dependent children and their parents.

This bill was referred to the Committee on Public Welfare.

SENATE 11. Bill to provide for medical and hospital services and medicines for total and permanent disability cases under the workmen's compensation law.

This bill was referred to the Committee on Labor and Industries; the hearing will be held on February 2.

SENATE 62. Bill permitting the registration without examination of certain graduate nurses.

This bill was referred to the Committee on Public Health.

BRAINARD F. CONLEY, M.D., *Chairman*
Committee on Legislation

COMMITTEE ON MATERNAL WELFARE

ANALYSIS OF CAUSES OF MATERNAL DEATH IN MASSACHUSETTS DURING 1941

TRANSFUSION REACTIONS

During 1941, 4 deaths were attributable to reactions from incompatible transfusions.

The first case was associated with complete premature separation of the placenta at thirty-five weeks. The patient, who was twenty-nine years old, had had four previous pregnancies. The first went to term; a living child was obtained, and there were no complications. In the second, third and fourth pregnancies, the babies were born prematurely and were jaundiced, all of which suggests erythroblastosis foetalis. During this pregnancy there had been a little bleeding at the thirtieth week. The patient started labor prematurely and entered the hospital with intact membranes and slight bleeding, which continued with each contraction. When fully dilated, a macerated fetus and a completely separated placenta were delivered spontaneously; this was followed by massive hemorrhage and profound shock. An intravenous injection of glucose, to which the patient responded well, was followed by a 350-cc. transfusion of blood from her husband; the typing and cross-matching were done in the usual rapid fashion, but no incubation of the cross-matching was carried out. The transfusion seemed to have little or no effect. Three hours later, the patient's pulse again became very weak; she was given 500 cc. of blood from a registered donor, but the presence of Rh agglutinins and agglutinogens was not determined. The condition of the patient improved for three days; then she again became weak and was given 500 cc. of blood from her brother-in-law, which was again cross-matched in the usual rapid fashion but no test for Rh agglutinins and agglutinogens was done. Immediately following this transfusion the patient had a violent chill. The respiration became rapid, deep and labored; and from then on she went steadily downhill. A large trace of albumin appeared in the urine, and the sediment contained many casts; the nonprotein nitrogen was 300 mg. per 100 cc. Death occurred twenty-four hours later. An autopsy showed "hemolytic infiltration of the uterine wall, amyloid infiltration of both kidneys and spleen, and generalized edema." This death was apparently due to transfusions of blood,

none of which were tested for the presence of Rh factor; this is supported by the fact that the patient's previous three children had presumably suffered from erythroblastosis foetalis.

The second case was that of a woman who had had six previous pregnancies. The first three were normal. In the fourth, the baby died fifteen hours after birth. In the fifth, a cesarean section was performed because of placenta previa; and following the sixth, because of bleeding, a transfusion was given, presumably from a compatible donor. The patient was delivered vaginally, and the baby lived six hours. The baby showed typical signs of erythroblastosis. After the birth of the baby, the uterus was examined internally and a small rupture at the site of the previous cesarean section was found. A hysterectomy was immediately done. The patient was transfused, but an hour later she vomited blood, bled from the abdominal wound and went into profound shock. A total of 1600 cc. of blood was given, but the bleeding continued. The patient became anuric and jaundiced. Bilateral decapsulation of the kidneys was performed on the eleventh day. There was some improvement in the output of urine, but the patient continued to go downhill and died on the fifteenth day after delivery. It seems likely that this death was due to an Rh reaction.

The third case was that of a patient who had had one previous full-term normal delivery. In this pregnancy, the patient is said to have suffered a post-partum hemorrhage. Ten days after delivery, moderate bleeding again occurred, and a transfusion was given. Death occurred shortly thereafter and was probably due to an anaphylactic reaction, possibly involving the Rh factor.

The fourth case was that of a patient who had had a normal convalescence after a low-forceps delivery at term. Three and a half weeks after discharge from the hospital the patient was readmitted because of an abscess in the right breast. This was opened, and a culture showed *Streptococcus haemolyticus* and *Staphylococcus aureus*. A blood transfusion was followed by a severe reaction; a second transfusion was given twenty-four hours later. The patient developed anuria, with non-protein nitrogen of 80 mg. per 100 cc., and apparently died because she had been transfused with an incompatible blood.

These four cases evidence the seriousness of blood transfusion. It should never be done until it is certain that the blood is truly compatible. Two of these cases show that the Rh factor is the underlying cause of many anaphylactic deaths.

DEATH

HICKEY — JOHN J. HICKEY, M.D., of Peabody, died January 17. He was born in Marblehead and was in his

seventy-sixth year. He received his degree from the Harvard Medical School in 1903.

Dr. Hickey was a staff member of the Josiah B. Thomas Hospital and the North Shore-Babies Hospital. His memberships included the Massachusetts Medical Society and the American Medical Association.

His widow, three daughters and two brothers survive him.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATHS

CONANT — MARY C. CONANT, M.D., of Lyme, died August 26. She was in her seventy-first year.

Dr. Conant, the daughter of Jonathan J. and Martha (Howard) Conant, was born in Thetford, Vermont, and graduated from the Woman's Medical College of Pennsylvania in 1899. She carried on an institutional practice in Pennsylvania and New York for many years, and moved to Lyme in 1932. She was a member of the New Hampshire Medical Society and the American Medical Association.

She is survived by a brother and three nieces.

DAY — ARTHUR K. DAY, M.D., of Concord, died on December 31, 1942. He was in his eighty-first year.

A native of Dover, he moved to Concord in 1868 and had been a resident since.

He was a graduate of Harvard Medical School in 1889, and for twenty-five years served as attending physician at the Margaret Pillsbury General Hospital in Concord. During the Spanish-American War he served in the United States Army as a first lieutenant and assistant surgeon. Dr. Day was the school physician of Concord for a number of years.

Besides his widow, he is survived by a daughter, Miss Helen D. Day, and two sons, Captain Philip S. Day, U.S.A., and the Rev. Robert B. Day, of Niagara Falls, New York.

FROST — GILMAN D. FROST, M.D., of Hanover, died October 8. He was in his seventy-ninth year.

Dr. Frost, son of Dr. Carlton P. and Eliza (A. DuBois) Frost, was born in Randolph, Vermont, and graduated from Dartmouth Medical School in 1892. He had been a prominent member of the faculty of Dartmouth Medical School, having served as professor of anatomy from 1894 to 1910, as professor of clinical medicine from 1910 to 1937, as secretary and treasurer of the school from 1896 to 1904 and as treasurer from 1904 to 1909. For a number of years he was health officer of Hanover. He was a member of the New Hampshire Medical Society and the American Medical Association.

He is survived by his widow and four children.

HUTCHINSON — HERBERT S. HUTCHINSON, M.D., of Milford, died November 26. He was in his ninety-fourth year, and when he retired from active practice, a month before his death, he was the oldest practicing physician in New Hampshire.

Dr. Hutchinson, son of Stillman S. and Emeline G. (Lull) Hutchinson, was born in Milford in 1849 and graduated from Dartmouth College in 1875 and from Bellevue Medical College in 1880. He joined the New Hampshire Medical Society in 1882, and received the organization's fifty-year medal a decade ago. He was also a member of the American Medical Association.

He is survived by two sons.

MISCELLANY

TUBERCULOSIS AND THE WAR
—HERE AND ABROAD

Information from countries in the war area regarding present health conditions is limited and unsatisfactory. In certain European countries extreme hardship is being undergone, owing especially to nutritional inadequacies. Evidence is already appearing that the sharp rise in tuberculosis encountered during the last war may again be expected, and with increasing severity. Although the death rate from tuberculosis in the United States showed its usual decline last year, increasing effort must be made to maintain this favorable situation.

The United States

The world conflict of 1914-1918 for the first time revealed tuberculosis as a major problem. From the early discovery of large numbers of tuberculous troops in the French army to the final assemblage of mortality records of the war years in the civilian population of all countries engaged, it was evident that tuberculosis was exacting a great toll, unrecognized in the wars of previous years. There is every reason to believe, however, that long wars accompanied by privation have always led to an increase in tuberculosis. Crowding, malnutrition, exposure to infection and hardship of every sort have been considered responsible in different degree.

Fortunately, a quarter of a century of research since World War I has led to a better understanding of methods for the control of tuberculosis. Countries fearing the ultimate outbreak of hostilities, through the tense years preceding their final advent, anticipated tuberculosis as a grave menace and prepared accordingly. But in spite of forewarning and preparation, a rise in tuberculosis mortality rates appears already evident. Modern war is total war. Whole populations are engaged, through accelerated industry as well as actual combat.

In World War II, increasing effort is being made in the United States to avoid the induction of soldiers with tuberculosis. Measures ensuring a very examination of practically all recruits admitted to the armed forces are in effect.

In the civilian population, precautions are being taken against nutritional deficiency, since it is almost universally believed to have important bearing on the problem of resistance to tuberculosis. However, malnutrition may not be the gravest predisposing factor in a rise of tuberculosis. The acceleration of industry, leading to crowded quarters in industrial districts, brought about by mass migrations to industrial centers, has created another opportunity for widespread infection.

It is evident that a grave menace exists of another worldwide recrudescence of tuberculosis. Its prevention will require vigorous effort against the spread of infection and all measures possible to maintain a high level of resistance to disease. (Long E. R. *War and tuberculosis* *Am Rev Tuberc* 45 616-636, 1942)

Britain

To what extent the tubercle bacillus will repeat its former triumph of a generation ago in Britain cannot yet be properly gauged, but it has taken the initiative and the future course of events will be greatly determined by the effort put forward by tuberculosis workers.

Deaths from respiratory tuberculosis increased about 6 per cent the first year of the war, and 10 per cent the second, while the increase in deaths from other forms

of tuberculosis was 2.4 per cent the first year, and 17.6 per cent the second.

A considerable amount of infection is evidenced among the general population, particularly children, which means that either the infecting dose is large or the resistance low. Both causes may have operated in the first half of 1941 when the mighty bombing of towns and cities made contact infection probable and frequent. However, if the increase is found to have continued since more normal conditions have prevailed, it will strengthen the idea that there has been a general lowered resistance to infection in children under five. Many factors may have contributed to the lowering of resistance in children, among which are change in diet, nonpasteurized milk, blackout and shelter conditions, and lack of sleep and rest.

Comparing the trend of events during the first three years of the last war and the available figures for World War II, a definite similarity can be traced, although living conditions now are probably more conducive to the spread of tuberculosis. However, there are some marked differences. Tuberculous meningitis has increased sharply, whereas in the corresponding period of the last war it fell almost to the prewar level. A further point of difference is the small variation between the male and female curves.

These are ominous signs, which mean that infection is lurking in hidden places and taking its toll, especially in infant lives, and which emphasize the urgency of means for discovering these nests of infection and the need for their adequate control. (Heaf, F., and Rusby, L. *A further review of tuberculosis in wartime* *Tubercle* 23 107-130 1942)

France

Food rationing started throughout France on October 1, 1940, when the following foods were restricted: bread, meat, cheese, fats, sugar, milk, chocolate and milled products. Technically other foods could be obtained, but in reality it was difficult to get them. The results of a survey carried on by the Institut des Recherches d'Hygiène on how different families of Paris were feeding themselves showed a total caloric insufficiency of about a thousand calories daily, a calcium deficiency and a calcium phosphorus imbalance, and an insufficient intake of Vitamin A.

Undoubtedly morbidity and mortality from tuberculosis have noticeably increased in Paris. The percentage of rapidly developed tuberculosis has gone up in an alarming manner. Comparing the figures of the first six months of 1941 with the corresponding ones in 1939, the mortality from tuberculosis increased 10 per cent.

Four basic diets were prescribed for sick persons in four specific categories. To lessen the ill effects on persons with active tuberculosis and known lesions, a diet was given that corresponded to their general category, plus a supplementary amount consisting of 45 gm of meat and 15 gm of fat daily per patient. Despite the precaution indicated the march of tuberculosis up to October, 1941, had been ominously progressive, thus if the present dietary regime continues and the consequences increase, the problem of tuberculosis in France will be exceedingly grave. (Minoli, R. F. *Food rationing and mortality in Paris 1940-41* *Mill and Mem Fund Quart* 20 213-220, 1942)

Canada

The fall in the death rate from tuberculosis in Canada, which has been so evident for the past quarter of a

century, has occasioned in some quarters a false sense of security. Nothing could be more unsound or misleading. A disease that kills nearly 6000 of the population, leaves at least 30,000 incapacitated, and costs the country directly at least \$8,000,000 annually is still a formidable enemy and a major public-health problem.

If control of tuberculosis is to be maintained in wartime, tuberculosis services must be continued, problems that arise as a result of the war must be attacked and advantage taken of wartime case-finding projects. Case finding has kept ahead of treatment facilities, which have been inadequate, and until both are developed to a greater degree, control of tuberculosis is still hidden in the future.

Two of the most important phases of case-finding services available are for the general practitioners to provide an early diagnosis, since this is still the greatest source of cases, and examination of contacts, the next greatest source.

Two opportunities have presented themselves as a result of the war: the x-ray examination of all recruits for the armed forces and case-finding projects among industrial workers, particularly in war industries. Tuberculosis is two and a half times as great in industry as in the general population. Therefore, the control of tuberculosis is an important phase of industrial hygiene.

Emphasis is being placed on retaining the open case of tuberculosis in sanatoriums. Every patient who leaves against advice represents a weakness in the tuberculosis-control system. The factors involved should be carefully analyzed and every way possible must be sought to remedy conditions in institutions to offset this failure in efficient segregation. (Wherrett, G. J. *The control of tuberculosis in wartime*. *Canad. Pub. Health J.* 33:438-445, 1942.) — Reprinted from *Tuberculosis Abstracts* (January, 1943).

CORRESPONDENCE

SUSPENSION OF LICENSE

To the Editor: This is to inform you that on January 20, 1943, the Board of Registration in Medicine voted to suspend for one month the license to practice medicine in this Commonwealth of Dr. Louis R. Medverd, 1210 Cambridge Street, Cambridge, Massachusetts.

State House
Boston

BOOK REVIEWS

Source Book of Medical History. Compiled, with notes, by Logan Clendening, M.D. 8°, cloth, 685 pp. New York: Paul B. Hoeber, Incorporated, 1942. \$10.00.

There have been forthcoming in recent years several medical source-books, but none, however, with quite the range of this one. It aims at the whole of medicine, starting with the Egyptian papyri and ending with Roentgen, so that there is something in it for every man who finds pleasure and profit in reading,—if not *ipsissimis verbis*, the next thing to it,—a first-hand translation of what many important contributors to medical science had to say.

True, neither this nor any other book of the sort can attain perfection in every eye. There will be complaints no doubt that this has been left out which ought to have been included, and that that has been inserted which has

left too little space for something else. And, as is always the case, there are authors who suffer from the brevity of their allotted room—men, if you will, who lend themselves ill to cutting. Pasteur is one such.

But it would be ungrateful to complain too much; and in all this is a noteworthy and valuable assemblage of material, a great deal of which is inaccessible elsewhere. To list the distinguished contributors would be a pleasure, but space does not permit. For each, the editor has furnished a brief note to assist in placing man and matter in historical position, and for those who would go farther in any particular direction he has listed references.

This volume also deserves commendation as a piece of bookmaking. But, if a personal note may be hazarded the price, even in an era of increasing costs, seems a little high. There are no plates to add to the publishing expense, and it is a pity that the cost will be a deterrent to many who would like to see it on their shelves.

Medical Diseases of War. By Sir Arthur Hurst, D.M. (Oxon.), F.R.C.P. With the co-operation of H. W. Barber, M.B. (Cantab.), F.R.C.P.; H. B. F. Dixon, M.D. (Dub.), F.R.C.P.; F. A. Knott, M.D. (Lond.), M.R.C.P. T. A. Ross, M.D. (Edin.), F.R.C.P.; and Arnold W. Stott M.A. (Cantab.), F.R.C.P. Second edition. 8°, cloth, 42 pp., with 8 plates. Baltimore: The Williams and Wilkins Company, 1941. \$5.50.

This book, a new edition of one first published in 1916 and later republished in 1918, will be found especially helpful to neurologists and to all interested in the neuroses of war. It is largely based on the author's wide experiences in World War I as neurologist to Guy's Hospital, commanding officer of the Seale-Hayne Hospital for Functional Nervous Disorders and consulting physician to the Salonica Army.

When one realizes that almost 6 per cent of 341,025 discharges from the British Army (from 1914 to the end of April, 1918) were due to war neuroses, the importance of recognizing and treating these cases correctly is evident. Hurst's remarks in Chapter I, "Predisposing Causes of War Neuroses," will repay careful reading. Other chapters follow: "Hysterical Symptoms in Soldiers," "Hysterical Contractures," "Hysterical Postures and Gaits," "Hysterical Tremors" and "Hysterical Blindness," with numerous brief case records, which are instructive. Many results and cures were almost miraculous.

Of especial interest is Chapter XVI, "Anxiety Neurosis of War," by T. A. Ross. Here, in particular, psychotherapy, with explanation to the patient, persuasion and re-education, worked wonders. The chapter on "soldier's heart" is excellent; in great measure, it is based on Sir Thomas Lewis's book, published in 1918. The section by H. W. Barber, on skin disease, is of particular value and importance.

Although this volume is supposed to discuss the medical diseases of war, almost half is given over to the neuroses and almost another half to a number of medical diseases such as trench fever, typhoid and paratyphoid fevers, bacillary dysentery, epidemic jaundice and tetanus, that will probably be of little importance in World War II, because conditions are so different from those in 1914-1918. Epidemics and perhaps pestilence will probably occur, but they are to be expected among the civilian populations.

Of great value at the end of each chapter are references to the published literature. An index also adds to the general usefulness of the volume. It can be recommended to those who are interested in military medicine.

NUMBER 5

PYOGENIC LIVER ABSCESSSES DUE TO *KLEBSIELLA PNEUMONIAE* (FRIEDLAENDER'S BACILLUS)*

THOMAS D. KINNEY, M.D.,† and HAROLD S. GINSBERG, M.D.‡

BOSTON

FRIEDLAENDER'S BACILLUS has not often been recognized as an etiologic agent in liver abscesses. In 1892, Potter¹ reported the finding, at autopsy of a sixteen year old girl, of a liver abscess from which *Klebsiella pneumoniae* was recovered. Other cases have been reported by Chaher,² Courmont, Dujol and Devic,³ Elrison,⁴ Carnot, Dumont and Libert,⁵ Le Sourd and Drulard,⁶ Hegler and Nathan,⁷ Bachr, Schwartzman and Greenspan,⁸ Boettger, Weinstein and Werne⁹ and Rothenberg and Linder.¹⁰ In none of the cases was there any mention of the serologic type of the organisms recovered. It is the purpose of this paper to report 7 cases with autopsy findings in which serologic studies were carried out in an effort to identify the type of *K. pneumoniae*.

MATERIAL

The material presented is selected from 5699 autopsies performed during the years 1934 to 1941 inclusive at the Mallory Institute of Pathology of the Boston City Hospital. During this time, 52 cases with liver abscesses of all types were found, a general incidence of 0.9 per cent. It is of some interest to compare these figures with those reported by Keefer¹¹ from this institute in 1934-75 cases of liver abscesses in 10,309 autopsies, an incidence of 0.7 per cent, for the years 1896 to 1933 inclusive. Bacteriologic studies were carried out in 32 of the cases reported by Keefer. In no case was *K. pneumoniae* identified as the etiologic agent. In the present series, bacteriologic studies were carried out in 30 cases, and *K. pneumoniae* was identified in 7, or 23 per cent.

CASE REPORTS

CASE 1 C.B.T. (BCH 791,965), a 64 year-old man, was admitted on July 11, 1935, complaining of intermittent fever, chills and cough.

*From the Mallory Institute of Pathology, Boston City Hospital, and the College Medical School, and instructor in surgery, Tufts College Medical School. First was stant in pathology, Mallory Institute of Pathology, Boston City Hospital.
†First assistant in pathology, Mallory Institute of Pathology, Boston City Hospital.
‡First assistant in pathology, Mallory Institute of Pathology, Boston City Hospital.

Two months prior to admission, the patient noticed that his breath had a foul odor. He stated that he had lost 14 pounds. Two weeks before entry, he began to suffer from "nervous indigestion." This was followed a week later by the sudden appearance of attacks of severe chills, fever and sweating. These episodes lasted from 10 to 12 hours, after which he felt well until the next similar attack. Two days before admission, he developed a dry hacking cough. He also noticed thirst and polyuria. There was a history of diabetes of 3 years' duration.

On admission the temperature was 101°F, the pulse 98, the respirations 24, and the blood pressure 120/80. The patient was well nourished and normally developed. The skin was warm and dry. The breath had a disagreeable and nauseating odor. The teeth were absent. The tongue was dry and coated. The prostate was large and boggy. There was a left indirect inguinal hernia. The remainder of the physical examination revealed nothing of note.

The hemoglobin was 76 per cent (Sjoh), and the white-cell count was 13,600. A differential count showed 58 per cent polymorphonuclear leukocytes, 32 per cent lymphocytes, 9 per cent monocytes and 1 per cent eosinophils. A strain of *K. pneumoniae* that did not ferment lactose was cultured from the urine. The urine showed various quantities of sugar but was otherwise normal. The blood Kahn and Hinton reactions were positive. Agglutination tests for typhoid, typhus and undulant fever were negative. Fasting blood sugar determinations varied between 185 and 420 mg per 100 cc.

The patient remained on the ward for 13 days, during which he experienced a severe chill on alternate days. On two occasions a strain of *K. pneumoniae* that did not ferment lactose was cultured from the blood. Treatment was supportive. On the 13th day, the patient suddenly complained of marked shortness of breath. He became orthopneic and semicomatose, and died ½ hour after onset of these acute symptoms.

Autopsy (A 35 417) Nothing of note was found on external examination of the body. The liver, whose edge extended 8 cm below the xiphoid in the midline and 3 cm below the costal margin in the midclavicular line, weighed 2600 gm. The entire dome of the right lobe was fluctuant, and the capsular surface over this area was a mottled white and deep reddish blue. The capsular surface elsewhere was firm and a homogeneous reddish brown. On section of the right lobe, an abscess 12 cm in diameter was found. The cavity of the abscess con-

tained 150 cc. of thick, brownish-yellow glairy mucopurulent material, together with what appeared to be lumps of necrotic liver tissue. Sections taken from the wall of the liver abscess showed marked necrosis, with polymorphonuclear leukocytic and macrophagic infiltration. In sections taken from areas of the liver not adjacent to the abscess, large numbers of polymorphonuclear leukocytes were found in the sinusoids, together with small masses of bacilli, which were both intracellular and extracellular. There was a partially organized thrombus in one of the radicles of the hepatic arteries. Patchy groups of liver cells were vacuolated. The gall bladder and bile ducts were negative.

The spleen weighed 180 gm. The remainder of the gastrointestinal tract was not remarkable. There were also moderate atheromatous changes in the coronary arteries, an acute tracheobronchitis and aortic atherosclerosis.

K. pneumoniae and *Clostridium welchii* were grown from cultures of the liver abscess, pericardium, heart's blood, pleura and right upper lobe of the lung. The former did not ferment lactose.

CASE 2. G.K. (B.C.H. 952,616), a 45-year-old man, first entered the hospital on July 2, 1938, complaining of a weight loss of 30 pounds in 5 weeks. In March, he had had an attack of diarrhea during which he had from ten to twelve stools daily. In May, he began to suffer from sharp pain localized in the right lower chest along the anterior costal margin; this was definitely worse on coughing and respiration. In June, he began to suffer from anorexia and fatigue. The family and past histories were irrelevant, except for excessive use of alcohol.

Physical examination showed only slight right-upper-quadrant tenderness. The red-cell count was 4,400,000 with a hemoglobin of 85 per cent (Sahli), and the white-cell count was 12,600, with 75 per cent polymorphonuclear leukocytes, 19 per cent lymphocytes and 6 per cent monocytes. The blood Hinton reaction was negative. Nothing of note was found in the urine. On repeated tests of the stools 0 to +++ guaiac reactions were obtained; no parasites were found. Stool cultures were negative for pathogenic organisms. A blood culture showed no growth. Agglutination tests for the enteric group and *Brucella melitensis* were negative. A chest plate showed the right diaphragm to be slightly elevated.

The patient remained in the hospital 21 days. For the first 2 weeks he had a temperature that daily spiked to 101°F. but was afebrile during the 3rd week. Because he felt well, the patient left the hospital against advice.

The patient re-entered the hospital a month later, complaining of a recurrence of his original symptoms. He stated that his pain, which had shifted to the epigastric region, was gnawing, and that it was necessary for him to walk bent forward because of the pain. The temperature was 100.4°F., the pulse 104, the respirations 20, and the blood pressure 140/90. Physical examination was essentially the same as that at the time of his first admission.

The red-cell count was 3,310,000 with a hemoglobin of 61 per cent (Sahli), and the white-cell count was 18,800 with 78 per cent polymorphonuclear leukocytes, 4 per cent large lymphocytes, 17 per cent small lymphocytes and 2 per cent eosinophils. The white-cell count remained elevated during the remainder of the hospital stay. The alkaline blood phosphatase was 16.5 Bodansky units per 100 cc. The van den Bergh reaction was less than 1 mg.

per 100 cc. The nonprotein nitrogen was 25 mg., the phosphorus 2.7 mg. and the calcium 9.2 mg. per 100 cc. Nine stools gave + to ++++ reactions to benzidine. No parasites were found in the stools. The bleeding time was 4½ minutes, and the clotting time 5 minutes. A sputum culture yielded a Type 13 pneumococcus and an alpha-hemolytic streptococcus. A blood culture was positive for *K. pneumoniae*, which was not acted on by Type A serum.

An x-ray film of the chest showed an area of cloudiness at the tip of the right diaphragm. The gastrointestinal series was interpreted as showing a duodenal ulcer with periduodenal adhesions.

The patient had a high, spiking temperature during his hospital stay and continued to complain of abdominal pain and to suffer from profuse sweats. In spite of supportive treatment, he died on the 31st hospital day.

Autopsy. (M.L. 30830.) The body was that of an emaciated man. The peritoneal surfaces were smooth and glistening. The liver weighed 2840 gm. and was adherent over the right lobe to the diaphragm. Attempts to separate these adhesions resulted in the opening of abscess cavities, which were filled with glairy, yellow, purulent matter. The abscesses in the liver were multiple, and varied in diameter from 0.5 to 6 cm. These were abundant throughout the left lobe and the upper portion of the right lobe, the external portion being fluctuant over considerable areas. Some of the abscesses, on the other hand, were relatively firm. Most of them were made up of single large cavities, but others showed a central cavity with yellow, opaque extensions about the border into the neighboring liver tissue.

Histologic sections showed massive destruction of liver tissue, with complete obliteration of the hepatic architecture. Around the periphery of the abscesses were large numbers of polymorphonuclear leukocytes and lymphocytes that infiltrated the remnants of the intact liver tissue. Bacilli, both intracellular and extracellular, were present in the abscesses.

The stomach was adherent over the internal surface of the left lower and spigelian lobes and lobus quadratus. It was impossible to separate the stomach wall from the liver. The mucosa of the stomach, even that portion above the esophageal junction, was greenish black. Patches of green necrotic material occupied the summits of the rugae of the upper fundus, where the wall was adherent to the posterior surface of the liver. In the lower fundus, the surface was irregular and firm, without evidence of stomach wall, and section disclosed necrotic underlying liver tissue, with no evidence of stomach wall. The duodenum was normal. Sections from the portion of the stomach adherent to the liver showed the wall to be completely necrotic, whereas those from uninvolved areas of the stomach revealed no lesion. The spleen weighed 400 gm. and was somewhat soft in consistence, but was not remarkable otherwise.

In addition, there were moderate atherosclerosis of the coronary arteries, bronchopneumonia of the left lower lobe and atelectasis of both lower lobes.

K. pneumoniae was grown from the heart's blood and from the liver abscesses. The capsule of this organism was not affected by Type A serum.

CASE 3. C.F. (B.C.H. 931,709), a 71-year-old man, entered the hospital on February 27, 1939, too acutely ill to give an adequate history. The temperature was 101.4°F., the pulse was imperceptible, the respirations were 48, and the blood pressure was 80/60. The patient was in acute distress and markedly orthopneic, and the lips were

cyanotic. The skin was moist, cold and pale. The heart was enlarged to the left, and the sounds were muffled. Respirations were rapid and noisy, and there were fine, moist rales at the bases of both lungs. The abdomen was moderately distended, and the liver was enlarged to 5 fingerbreadths below the right costal margin. There was marked pitting edema of both legs. No laboratory work was performed.

The patient was given symptomatic and supportive treatment. He was digitalized rapidly. His condition became progressively worse, and he died the day after admission.

Autopsy (A 39 191) External examination of the body was negative. The liver weighed 1800 gm., was slightly increased in size and weight, was of a flabby consistence and was studded throughout by multiple, irregularly shaped abscess cavities containing very thick, mucoid yellowish brown exudate. The abscesses varied in diameter from 1 to 5 mm., and their walls were thin and shaggy. The wall of the gall bladder was markedly thickened, and the lumen contained three calculi varying from 10 to 14 cm in diameter. The common duct could not be identified. Histologic sections of the liver showed marked post mortem changes. There was a slight increase in the perportal connective tissue, together with moderate lymphocytic infiltration of these areas. There were multiple small abscesses in which the liver parenchyma was destroyed and replaced by polymorphonuclear leukocytes, bacilli and debris. The wall of the gall bladder was thickened by fibrous tissue and infiltrated by lymphocytes.

The spleen was markedly enlarged, weighing 1000 gm. and grossly showed no abnormalities. The splenic vein was normal. Microscopically, the pulp was diffusely infiltrated by polymorphonuclear leukocytes and markedly engorged by red blood cells.

The heart was moderately enlarged. There were pulmonary congestion and edema, and moderate benign prostatic hypertrophy.

Cultures from the hepatic abscesses revealed *K. pneumoniae* and an alpha hemolytic streptococcus. Splenic culture revealed *K. pneumoniae*. The heart's blood was not cultured. The capsule of the Friedlander's bacillus did not react with Type A serum.

CASE 4 W P (BCH 955,438), a 65 year old man entered the hospital on September 21, 1939. He was drowsy and orthopneic, and was unable to give any history. From the patient's physician, it was learned that, 1 month before entry, the patient had complained of malaise. Examination of the urine at that time gave a positive test for sugar, which cleared following a restricted diet. Approximately 10 days before entry, the patient developed painless jaundice. On examination, the liver edge was palpated 2 fingerbreadths below the costal margin, and there was right upper quadrant tenderness. Two days before admission, the jaundice became severer, and the patient became semistuporous.

At the time of admission, the blood pressure was 100/50, the pulse 110, the respirations 35, and the temperature 101.8°F. The patient was obese, stuporous, dyspneic and breathing with Cheyne-Stokes rhythm. He appeared to be in extremis. The skin and mucous membranes were markedly icteric. Moist rales were present over the entire lower two thirds of each lung. The liver edge was palpated 1 handbreadth beneath the costal margin and was tender on pressure. The remainder of the examination revealed nothing of note.

The red-cell count was 3,500,000 with a hemoglobin of 65 per cent (Sahli), and the white-cell count was 18,300

with 87 per cent polymorphonuclear leukocytes, 7 per cent lymphocytes, 5 per cent monocytes and 1 per cent eosinophils. The blood smear showed many young forms of the granulocytic series. The icteric index was 180. Tests for bile and urobilinogen were positive in 1:64 dilutions of the urine, which was otherwise normal. The blood Hinton reaction was normal. Lumbar puncture revealed nothing of note.

The patient was given supportive treatment but failed to respond and died a few hours after admission.

Autopsy (A 39 633) The body was that of a moderately well nourished and well developed man. There was marked icterus of the skin and sclerae. Examination of the peritoneal cavity was negative. The liver weighed 2400 gm. Several irregular mottled yellow areas beneath the intact capsule contrasted with the reddish brown parenchyma. On section, multiple abscesses, measuring a few millimeters to 8 cm in diameter, were present. Microscopic sections of the liver showed marked replacement of the liver cells by scar tissue. There was polymorphonuclear leukocytic and lymphocytic infiltration about the smaller bile ducts, with moderate polymorphonuclear leukocytic infiltration of the ducts. Sections taken from the edges of the abscesses showed massive tissue destruction, together with masses of polymorphonuclear leukocytes. Groups of bacilli were present in the abscesses and were both intracellular and extracellular.

The mucosa of the common duct was dull red, and sections showed slight polymorphonuclear leukocytic infiltration. There was no evidence of stone or obstruction in any of the large bile ducts. The gall bladder was enlarged but was thin walled, and microscopic sections showed a slight degree of chronic cholecystitis.

The spleen weighed 300 gm., but was otherwise normal. The pancreas was grossly normal, but microscopic sections showed focal areas in which the intralobular and extralobular fat was necrotic and infiltrated by polymorphonuclear leukocytes. There was also moderate focal infiltration by polymorphonuclear leukocytes between the acini.

Bronchopneumonia and benign nephrosclerosis were present.

Cultures from the heart's blood showed *Escherichia coli*, from the bile, *K. pneumoniae*, *Cl. welchii* and *Esch. coli*, from the liver abscesses, *K. pneumoniae* and *Cl. welchii*, and from the right and left lower lobes *K. pneumoniae*, pneumococcus (Type 29) and *Cl. welchii*. In each instance the *K. pneumoniae* showed no reaction with Type A serum.

CASE 5 E G (BCH 958,180), a 41 year old woman entered the hospital with a chief complaint of right upper quadrant pain radiating to the right subscapular region, and progressively increasing jaundice for the previous 3 days. The patient had been nauseated and had several bouts of vomiting before admission. No bile was seen in the vomitus. She had had no chills or sweating, but had had a fever. There had been no constipation or diarrhea. The stools were clay colored.

The patient had had many previous admissions to the hospital, several for rheumatic heart disease with mitral stenosis, auricular fibrillation and symptoms of decompensation, for which she was given digitalis. For the preceding 15 years, she had had symptoms relating to the biliary tract, for which she first had biliary drainage with removal of gallstones and later cholecystectomy and removal of calculi from the common duct. She had continued biliary symptoms with operations for removal of common-duct stones, and finally anastomosis of the com-

mon bile duct to the duodenum was performed 7 months before admission, because of a stricture of the common duct.

The blood pressure was 120/80, the temperature 103°F., the pulse 100 to 120, and the respirations 30. The patient was markedly jaundiced, thin and dehydrated. The diaphragm was not elevated, and a few basal rales bilaterally were heard in the lungs. The heart was moderately enlarged to the left and right, and the rate was rapid and grossly irregular. No murmurs were heard, and there were no thrills. There was no rigidity of the abdomen. There was tenderness in the right upper quadrant and epigastrium, but no masses were felt. The liver and spleen were not palpable. Peristaltic movements were present. Otherwise, physical examination was negative.

The urine showed a slight trace of albumin, rare white cells, and a +++ test for bile, but was otherwise normal. The red-cell count was 3,580,000 to 3,260,000 with a hemoglobin of 70 per cent (Sahli), the white-cell count 18,000 to 29,800, and the icteric index 95. The fasting blood sugar was 96 mg. and the nonprotein nitrogen 47 mg. per 100 cc. The stools were clay colored. The blood Hinton reaction was negative.

The patient was placed on bed rest, with a high-carbohydrate intake. She was given one injection of vitamin K intramuscularly. She seemed to be improving but the jaundice did not decrease. On the 3rd hospital day she became very orthopneic and disoriented, and died on the following day.

Autopsy. (A-40-541.) The body was that of a well-nourished, markedly jaundiced woman. The peritoneal cavity contained no free fluid, and the surfaces were smooth and glistening. The liver weighed 2120 gm. and on section showed multiple abscesses scattered throughout, measuring from 0.4 to 1.5 cm. and filled with thick mucoid yellowish-green pus. Microscopically, sections showed marked necrosis of the parenchyma, with massive polymorphonuclear leukocytic infiltration and abscess formation. Many bacilli were present. The bile radicles were moderately dilated. The common duct was greatly dilated, measuring 3.0 cm. in circumference, and thickened, and had a functioning anastomosis to the duodenum. The gall bladder and cystic duct were absent. No calculi were found in the common duct. The spleen weighed 310 gm. and was normal.

There were healed rheumatic heart disease, with mitral stenosis, pulmonary congestion and edema, purulent leptomeningitis, and slight, healed pyelonephritis.

Cultures of the liver abscess showed *K. pneumoniae*. The capsule of this organism was not reacted on by either Type A or Type B serum. Cultures of the meninges yielded a Type 14 pneumococcus.

CASE 6. P. S. (B.C.H. 1,005,913), a 56-year-old man, entered the hospital on May 4, 1941, complaining of a "cold" of 3 weeks' duration. He had been previously treated for diabetes mellitus in this hospital in November, 1940, and discharged on diet and insulin. He apparently did well until 3 weeks before entry, when he developed an upper respiratory infection. Two days before admission, he began to suffer from severe, persistent left-upper-quadrant pain, together with loss of appetite and dizziness.

The temperature was 99.2°F., the pulse 90, and the respirations 22. The blood pressure was 110/80. Physical examination showed a man who presented evidence of weight loss. There were moist rales at the base of the left lung. There was a systolic murmur at the base of

the heart. A left indirect inguinal hernia was found. The remainder of the physical examination was negative.

The red-cell count was 4,400,000 with a hemoglobin of 88 per cent, and the white-cell count was 15,800 with 75 per cent polymorphonuclear leukocytes, 15 per cent small lymphocytes, 2 per cent large lymphocytes, 7 per cent monocytes and 1 per cent basophils. The blood non-protein nitrogen was 25 mg., the calcium 9.2 mg., the phosphorus 2.8 mg., and the alkaline phosphatase 5.8 Bodansky units per 100 cc. The blood Hinton reaction was negative. The urine was acid, with a specific gravity of 1.014, a slight trace of albumin and a moderate amount of sugar. The urinary sediment was negative. The stool gave a ++ guaiac reaction.

The hospital course was one of progressive decline. The diabetes was easily controlled, but the patient continued to suffer from left-upper-quadrant pain and anorexia. He was given therapeutic doses of sulfathiazole. He gradually became weaker and incontinent, and died on the 27th day after admission.

Autopsy (A-41-423). The body was that of a normally developed but rather emaciated man. External examination revealed nothing of note. There was 150 cc. of fibrinopurulent exudate in the peritoneal cavity, and the peritoneal surfaces were covered by similar exudate. The lower surface of the liver, both kidneys and adrenal glands, spleen and pancreas all formed part of a large mass bound together by fibrinopurulent material. In the lesser peritoneal cavity and extending retroperitoneally was a large abscess containing foul brown pus. The duodenum formed one wall of this abscess, but the lumen was not affected. The celiac and superior mesenteric arteries contained large friable thrombi almost completely filling their lumens. The splenic vein was completely occluded by a friable necrotic clot, together with considerable purulent material. The portal vein showed thrombosis and purulent matter, which could be traced into the parenchyma of the liver.

The liver weighed 2030 gm. The capsule was intact. The surface and parenchyma were deep red, spotted by many irregular, pale yellow gray areas, which measured from 0.2 to 5.0 cm. in diameter. The centers of many of these areas were soft and necrotic and filled by creamy yellow mucopurulent material. It was estimated that these pale areas occupied two thirds of the liver substance. Microscopically, sections from the liver showed many abscesses, with necrotic liver cells, polymorphonuclear leukocytes and bacilli. The majority of the abscesses appeared to originate in the portal spaces. The walls of the abscesses showed marked polymorphonuclear leukocytic infiltration.

The portal vein was lined by an organizing, centrally liquefied thrombus. There was diffuse polymorphonuclear leukocytic infiltration of the vessel wall and surrounding tissue. A section taken from the splenic vein showed essentially the same process.

The wall of the gall bladder was markedly thickened by fibrous tissue and averaged 0.8 cm. in width. At the fundus was a large pocket of pus, which was walled off from the lumen. The lumen of the gall bladder contained pale, mucoid, slightly purulent bile. There was diffuse lymphocytic infiltration of the wall. Throughout the wall were focal masses of polymorphonuclear leukocytes. The walls of the cystic and common ducts were thickened and contained pale bile similar to that in the gall bladder.

The pancreas was soft and friable, and contained many irregular, rough stones averaging 0.2 to 0.6 cm. in di-

ameter. Most of these stones were surrounded by brown pus and were contained in small cystic spaces.

Sections from the pancreas showed a large portion of the parenchyma to be replaced by masses of polymorphous nuclear leukocytes or diffusely infiltrated by lymphocytes and fatty macrophages. One section showed proliferation of atypical duct epithelium growing in a definitely circumscribed nodular arrangement. However the tumor was growing along a nerve sheath in one area. This was interpreted as an early adenocarcinoma of the head of the pancreas.

In addition to the above lesions, there were a chronic gastric ulcer and healed focal pyelonephritis.

K. pneumoniae was cultured from the heart's blood, the liver abscesses, the gall bladder and the peritoneal abscess. It reacted with Type A serum.

CASE 7. P. K. (BCH 1,033,118), a 71-year-old man, was admitted in a semistuporous condition on July 19, 1941. Three weeks previously, he experienced a sudden onset of vague upper abdominal pain, which persisted for 1 day. The pain was accompanied by a temperature of 101°F and was followed by slight jaundice which disappeared after 2 days. The patient was treated with sulfanilamide and digitalis. The pulse and temperature became normal, the sulfanilamide was omitted but the digitalis was continued. The patient remained drowsy, however, and the only complaint was that of difficulty in urinating. On the evening before entry, he had a shaking chill and the temperature rose to 103°F. The past history was irrelevant.

At the time of admission, the temperature was 97.8°F, the pulse 80, and the respirations 20. The blood pressure was 110/54. Physical examination revealed a very acutely ill, well-nourished, stuporous man. The trachea was deviated to the left, and there was marked limitation of expansion of the entire left chest over the same area; there were dullness to flatness, diminished breath sounds and diminished tactile fremitus. The heart sounds were distant, and the cardiac rhythm was regular. There was a short, rough, systolic apical murmur transmitted to the axilla and base. The abdomen was soft and rounded. A sharp, firm, nontender liver edge was felt 3 cm below the right costal margin. There was no tenderness or spasm. The prostate was symmetrical, movable moderately enlarged and nontender. The remainder of the physical examination was negative.

Examination of the urine revealed specific gravities varying between 1.006 and 1.020, a mild albuminuria and persistent moderate pyuria. Urine cultures consistently showed *K. pneumoniae*, *Esch. coli* and enterococci. Examination of the blood showed a red cell count of 2,900,000 with a hemoglobin of 62 per cent (Sahli), and a white-cell count of 16,000 with 53 per cent polymorphonuclear leukocytes, 36 per cent band forms, 2 per cent metamyelocytes, 1 per cent myelocytes, 1 per cent basophils, 3 to 5 per cent lymphocytes and 3 to 5 per cent monocytes. The mean corpuscular volume was 107 cu microns, the mean corpuscular hemoglobin concentration 31 per cent, and the mean corpuscular hemoglobin 33 microgm. The blood Hinton reaction was negative. The total serum protein was 5.6 gm per 100 cc, with an albumin/globulin ratio of 1.0. The icteric index was 3. The formal gel test was weakly positive. A bromsulphalein test showed 70 per cent retention of the dye in 5 minutes and 20 per cent in 15 minutes. The prothrombin time was normal and urobilinogen was present in the urine in a 1:2 dilution. Blood culture revealed no growth.

Gastric analysis showed 32 units of free acid before and 92 units 1 hour later. The fluid was guaiac negative. Guaiac tests of the stools were repeatedly negative.

A roentgen study of the chest was negative. A gastrointestinal series was interpreted as showing an old duodenal ulcer, with perigastrophic adhesions and a hiatus hernia. A spot film of the gall bladder showed no evidence of gall stones. Two barium enema studies were unsatisfactory.

The patient remained semistuporous throughout his hospital stay. During the 1st week, he had three shivering chills, the temperature spiking from 102 to 103°F. Sulfadiazine therapy was instituted, and blood concentrations reaching 10 mg per 100 cc were attained. During the 2nd week the patient was afebrile, and sulfadiazine was omitted. During the ensuing 3 weeks he had intermittent low grade fever. Accordingly, sulfadiazine was started again and continued for about 2 weeks, after which, because of continued fever, sulfathiazole was substituted and continued until the patient's death. The laboratory and physical findings remained essentially unchanged during the final 2 days in the hospital; the patient began to vomit and became comatose. The nonprotein nitrogen rose to 83 mg and the sulfathiazole level to 21 mg per 100 cc, and the patient died quietly at the end of the 10th week in the hospital.

Autopsy (A 41,643). External examination of the body revealed nothing of note. The liver weighed 1600 gm. The capsule was smooth and glistening, and through it could be seen small, irregular areas, lighter in color. On section, numerous abscesses ranging from 2.5 to 5.0 cm in diameter were seen throughout the right quadrate and caudate lobes. These abscesses were filled with a greenish yellow, thick, tenacious exudate with a glairy appearance. The walls of the abscesses were irregular and contained fibrous connective tissue microscopically. The walls of the abscesses were diffusely infiltrated by polymorphous clear leukocytes, and many bacilli were present. Patchy cholangitis of the small ducts and a slight degree of old biliary cirrhosis were noted. The gall bladder was small and almost entirely embedded in the liver substance. The walls were thickened to 4 mm and, microscopically, were found to be studded with minute intramural abscesses. The lumen contained numerous faceted pigment calculi measuring up to 3 cm in diameter, which were bathed in an exudate similar to that found in the liver abscesses. The common bile duct, which was slightly dilated, contained bile but no calculi. The portal vein showed no evidence of phlebitis.

There was no evidence of inflammation about the appendix or the numerous diverticula of the sigmoid colon. The spleen weighed 60 gm and was normal. The kidneys showed a slight amount of chronic pyelonephritis and retention of sulfathiazole crystals in the pelvis. The prostate contained active infection and at least one healing abscess. Unfortunately, no culture was taken. There were moderate edema and congestion of the lungs. The heart was negative. The vertebral bone was quite fatty and hypoplastic.

No organisms were cultured from the heart's blood. *K. pneumoniae* was cultured from the liver, the liver abscesses and the gall bladder, the strain reacted with Type B serum.

DISCUSSION

A careful study was made of the clinical histories, signs and symptoms of our cases and of

those reported in the literature. No single sign or symptom was found that would distinguish liver abscess due to *K. pneumoniae* from those in which the usual pyogenic organisms were the etiologic agents.

The only laboratory finding of value in the diagnosis of liver abscess due to *K. pneumoniae* was the blood culture, which was positive in 11 of 23 cases reported in the literature. In the cases reported above, ante-mortem blood cultures were taken in 6, and *K. pneumoniae* was recovered in 1.

Pathology

The gross appearance of the liver abscess due to *K. pneumoniae* is, except for the exudate, similar to that in abscesses caused by other pyogenic organisms. In all but 1 of the cases presented above, there was multiple abscess formation. Of the 23 cases in the literature, the livers in 2 contained a single abscess. Two abscesses were found in one case, and three in another, whereas the livers of the remaining cases showed multiple abscess formation.

The exudate in all the cases presented above was characteristically glairy and mucoid. The exudate appears similar in all respects to that seen in *K. pneumoniae* infections of other parts of the body.

Microscopically, there is nothing to distinguish these abscesses from other pyogenic liver abscesses except for the finding of organisms with the morphology of *K. pneumoniae*.

Disease of the biliary system other than the liver was present in 4 of the 7 cases in the present series, in only one of which (Case 5) there was definite obstruction of the common bile duct; another (Case 6) was associated with acute suppurative cholecystitis and cholelithiasis, acute suppurative pancreatitis, early adenocarcinoma of the head of the pancreas and acute pyelophlebitis. Case 7 was associated with acute empyema of the gall bladder, with cholelithiasis but no infection of any of the hepatic bile ducts. Case 3 was associated with chronic cholecystitis with cholelithiasis. In Case 2, the abscess resulted from direct extension from the stomach. It appears from this small series of cases that the pathogenesis of liver abscesses due to *K. pneumoniae* is varied and is similar to that of other pyogenic liver abscesses. In Cases 1 and 4, there was no associated biliary, gastrointestinal or urinary-tract infection.

Only 15 cases were found in the literature with reports complete enough to allow consideration of etiologic factors. Ten were associated with extra-hepatic biliary disease. Of the remaining 5 cases, 1 was complicated by bronchopneumonia and empyema due to *K. pneumoniae*; 1 followed acute

appendicitis, and 1 was associated with bronchiectasis and lung abscess from which Friedländer's bacillus was cultured. In the other 2 cases, no definite source of infection could be determined.

Bacteriology

Until recent years, *K. pneumoniae* has been associated in the minds of most observers as occurring primarily in the upper respiratory tract. This undoubtedly is largely because Friedländer,¹² in first describing the organism in 1882, named it the pneumobacillus and regarded it as the etiologic agent in lobar pneumonia. Even after Weichselbaum¹³ demonstrated that the pneumococcus was the cause of lobar pneumonia, *K. pneumoniae* was always considered the agent responsible for a particularly malignant type of lobar pneumonia. Very little attention was given to the organism as an infective agent in other parts of the body, although numerous reports described the bacillus as causing suppurative lesions in practically every organ of the body. It has also been described as occurring in many domestic animals.

In 1937, Baehr, Schwartzman and Greenspan⁸ reported a study of 198 cases of infection with Friedländer's bacillus. In this series, there were 25 cases of lung or upper-respiratory-tract infection, only 2 of which were cases of pneumonia in which the clinical and bacteriologic evidence indicated that *K. pneumoniae* was the primary cause of pneumonia. In 7 other cases of pneumonia, the authors recovered this organism in association with the pneumococcus or streptococcus. It is the experience of this laboratory that Friedländer's bacillus usually occurs as a secondary invader rather than as the primary organism in cases of lobar pneumonia and bronchopneumonia. In the series of Baehr, Schwartzman and Greenspan, the bacillus occurred in the gastrointestinal tract in 61 cases, in the genitourinary tract in 56, and in the biliary system and liver in 46.

It has been pointed out by Dudgeon¹⁴ and Kendall¹⁵ that the Friedländer bacillus is often found as a normal inhabitant of the intestinal tract.

The cultural and morphologic characteristics of the Friedländer bacillus are well known and need not be described here. However, comparatively little attention has been given to the type specificity of the various strains of this organism and to their clinical significance. Many unsuccessful attempts have been made by various investigators to arrive at a satisfactory classification of the Friedländer group by fermentation of the sugars. It was not until Julianelle,¹⁶ in 1926, developed a serologic classification that any order was brought to this group. He found that there are three sharply defined and specific types and one heterogeneous

group of *K. pneumoniae*, and that the agglutination, agglutinin adsorption, protection, thread and precipitin reactions are highly specific for each type. Edwards,¹⁷ who was able to confirm the work of Julianelle, demonstrated only two serologic types; a Type 1, which was mainly of equine origin and corresponded to Julianelle's Type B, and a Type 2, which was of human origin and corresponded to Julianelle's Type A.

Julianelle¹⁸ carried out further work in which he studied eighty strains of *K. pneumoniae* gathered from various sources. He found 52 per cent to be Type A, 15 per cent Type B, 9 per cent of Type C and 24 per cent Group X. Type A, for the most part, consisted of strains derived from man, and more than 70 per cent of these were associated with pneumonia in human beings. The greatest number of Type B strains came from animal sources. The strains from heterogeneous Group X were found in a great variety of diseases.

Before the serologic typing of the organisms in the cases presented is discussed, it should be pointed out that Type A serum has been available here only since 1939, whereas Type B serum was first obtained by this laboratory in 1940. To date, Types C and X serums have not been obtainable.

Of the 7 cases presented above, the organism in only 1 case (Case 6) reacted with Type A serum. This is of particular significance, because this type, in the experience of this laboratory, is usually associated with respiratory infections. According to Perlman and Bullock,¹⁹ of 37 cases of Friedländer pneumonia, 29 were caused by Type A and only 8 were caused by Type B. Solomon^{20,21} reported similar results: in 9 cases of chronic Friedländer pneumonia, 7 were caused by the Type A strain, 1 by the Type B and 1 by the Type C; and in 10 cases of acute Friedländer's pneumonia all were caused by the Type A strain.

The organism in Case 7 belonged to Type B. Again, there were no lung lesions and the blood culture was negative.

The bacilli from Cases 2, 3 and 4 were not reacted on by the Type A serum, and therefore belong to Type B or C or Group X, whereas the capsules of the organisms in Case 5 did not swell in the presence of either Type A or B serum. The patient in Case 1 was autopsied before any serum was available, and thus the organism was not serologically typed. However, it was not a lactose-fermenting organism, and it has been the experience in this laboratory that the Type A organisms are lactose fermenters.

Recently, a case of common-duct obstruction with pericholangitis and empyema of the gall bladder came to autopsy. Friedländer's bacillus was

cultured from the liver and the gall bladder. This organism was not reacted on by either the Type A or the Type B serum.

To summarize, 1 case of biliary tract infection was infected with the Type A organism, whereas 6 were definitely not. To this group, the case that was not typed could in all probability be added. Of these 7 cases, 3 are known definitely not to belong to Type B. Although the number of cases presented is too small to draw definite conclusions, it is interesting to draw attention to the large preponderance of organisms other than those classified as Type A in these hepatic infections.

SUMMARY

Seven cases of liver abscess due to *Klebsiella pneumoniae* (Friedländer's bacillus) are reported, and the autopsy and bacteriologic findings are discussed. One case of empyema of the gall bladder and cholangitis due to Friedländer's bacillus is mentioned.

The significance of the serologic typing of Friedländer's bacillus is discussed. In the cases presented, all but one of the organisms belonged to serologic groups other than Type A.

THE FAILURE OF COBRA VENOM TO RELIEVE PAIN IN RHEUMATOID ARTHRITIS*

ROBERT H. TALKOV, M.D.,† AND WALTER BAUER, M.D.‡

BOSTON

PAIN is the greatest single factor responsible for restricted joint motion, subsequent muscle atrophy and articular deformity in rheumatoid arthritis. The course and outcome of this disease would presumably be more favorable if pain could be completely controlled. Unfortunately there is no analgesic capable of producing such an ideal situation, although the salicylates, especially acetylsalicylic acid (aspirin), administered in maximal dosage most nearly approach this goal.

The use of cobra venom was suggested by reports of its analgesic action not only in cancer¹⁻³ but also in various rheumatic diseases.^{2, 4} Macht¹ attributes its effect in human beings to a central action on the higher cerebral nerve centers. In comparison with morphine it is supposed to produce a more delayed but longer-lasting analgesia.

Moderate success has already been claimed for its use in arthritis. Although Macht² thought that the 10 arthritis patients treated by him formed too small a group to warrant discussion, he noted that "considerable relief of pain has been obtained in some instances." Steinbrocker and his associates⁴ reported that 11 of 13 patients with rheumatoid arthritis experienced slight to moderate improvement. Varying degrees of benefit were observed in other patients with degenerative joint disease, so-called "fibrositis" and "neuralgia." The reports of Burkhardt,⁵ who used intracutaneous injections of venoms from *Vipera aspis* and *Vipera ammodytes*, and that of Butler,⁶ who administered copperhead venom intradermally, are not sufficiently detailed to allow evaluation of their results. Because of the need of a more ideal analgesic in rheumatoid arthritis it has seemed advisable to attempt to corroborate the reports.

METHOD

Availability and the preliminary criteria for the selection of questionable clinical, laboratory and roentgenologic cases of rheumatoid arthritis. The patients, however, had no previous control, having

been treated for pain were the patients with uncontroverted x-ray evidence of disease. The patient served as his own control. The patient served for seven

morial for the hospital, the Department of Massachusetts Department of Health, Boston, Massachusetts. The investigation was supported in part by a grant from the Harvard Medical School, Boston, Massachusetts. General Medical School, Boston, Massachusetts.

months to several years before treatment. All were followed subsequently for four weeks to six months. Nine were hospitalized and on bed rest during the period of therapy; three were ambulatory, having been hospitalized previously. Physiotherapy and necessary orthopedic measures were continued, but acetylsalicylic acid was omitted in all but 1 case. All patients were seen daily by the same observer and evidence of objective as well as subjective improvement was noted. Measurements of pain thresholds were made in 4 patients. Laboratory data relative to blood cytology, urinalyses and corrected sedimentation rates⁷ were obtained in all cases.

Cobra venom§ was administered intramuscularly each day. Larger doses were employed than had been used by Macht¹ (5 mouse units daily until relief of pain was noted) and Steinbrocker et al.⁴ (10 mouse units daily to a total dosage of 50 units before considering the result a failure). Our first 2 patients received 10 units daily for four to six days, then 20 units a day for three to four days, and eventually 30 units every twenty-four hours. All other patients were given 10, 20 and 30 mouse units on each of the succeeding first three days and 30 units daily thereafter. A total of at least 300 mouse units was given in all cases, a dosage adequate to demonstrate any analgesic action of cobra venom.

RESULTS

The data of the individual cases are shown in Table 1.

Toxicity

No serious toxic effects were noted with the large doses employed. In Case 2, the patient experienced a transitory sedative effect on several occasions. Local reaction at the site of injection occurred in only 1 patient (Case 12). In this case, twenty minutes after each injection there appeared an irregular erythematous area, 2 cm. in diameter which was accompanied by local heat. There was marked local pain for five to twelve hours. After twenty-four hours a 1-cm. ecchymotic, slightly elevated, warm induration persisted, which slowly disappeared in the course of several days.

*Dr. David I. Macht of Hynson, Westcott and Dunning, Incorporated, Baltimore, Maryland, kindly supplied the cobra venom used in this study. The preparation contained 10 mouse units per cubic centimeter of solution.

CASE NO.	PATIENT	SEX	AGE	DURATION OF DISEASE	STABILITY OF DISEASE	PREVIOUS TREATMENT AND EFFECT	STATE OF DISSEMINATION	X-RAY FINDINGS	SEMIQUANTITATIVE RATE	TOTAL DOSE OF ACETYL-SALICYLIC ACID	ANALGESIC EFFECT OF COBRA VENOM	REMARKS	
									BEFORE THERAPY	AFTER THERAPY	COBRA VENOM		
									mm / min	mm / min	mm / min		
1	G. L. (No 18146)	M	26	4	Marked progress since	Hospitalization, outpatient measures, theophylline and Relaxin with temporary benefit	Exacerbation increased pain	Osteoporosis of spine, fusion of sacrospinous joints, narrowing of hips	0.46	0.52	345	Good	Hip pain increased while taking cobra venom, no objective changes, acetylsalicylic acid far superior
2	S. K. (No 00132)	M	22	8	Marked progress since (2 yr), in bed (1 yr)	Hospitalization and outpatient measures with slight benefit	Active constant pain in all joints	Narrowing of joint spaces with bony fusion in some	1.54	1.67	355	Poor	Less pain and stiffness noted after 175 units, no objective changes. Patient evaluated 50-75 per cent relief of pain occasionally felt sleep after an injection
3	A. B. (No 157841)	M	55	5	Marked progress since	Hospitalization, vitamin D, cobra venom and Relaxin (2 courses) with no benefit	Active constant pain in all joints	Irregular narrowing and destruction of wrists, hands and elbows	1.92	Not done	395	Poor	No subjective or objective change
4	M. V. (No 220589)	F	29	13	Moderate remission with pregnancy lasting 3 yr	None	Active exacerbation for 8 months moderate pain	Destructive changes of joint margins of some interphalangeal joints	0.74	0.72	440	Good	Claimed 25-50 per cent relief of pain, starting after 175 units, no objective changes as good results with acetylsalicylic acid
5	H. H. (No 127252)	F	49	10	Moderate remission in part for 5 yr	None	Active exacerbation, moderate pain in some joints	Decalcification of metacarpals and bony destruction of some	1.23	1.58	300	Fairly good	No relief of pain, acetylsalicylic acid superior
6	E. A. (No 327707)	F	40	3½	Moderate	None	Moderately severe pain in all joints	Destruction of some interphalangeal joints	0.91	0.86	300	Good	No relief of pain, acetylsalicylic acid superior
7	A. B. (No 321644)	F	53	2½	Marked progress since	Serum injections with no benefit	Active severe pain in all joints	Widened joint spaces, narrowing of many joints	1.25	1.1	300	Good	Increased pain while taking cobra venom, acetylsalicylic acid far superior
8	P. A. (No 150155) ambulatory	M	40	5½	Moderate	Hospitalization and outpatient measures with slight benefit	Mildly active in dermis, pain	Narrowing of left wrist and scapulothoracic joints	0.33	Not done	300	Fair	Increase in pain to point of incapacitation while taking cobra venom, acetylsalicylic acid far superior
9	H. N. (No 148322) ambulatory	F	29	10	Mild several remissions	Hospitalization, physiotherapy, and outpatient measures with moderate benefit	Mildly active with objective changes	New bone formation about scrotothoracic joints	0.36	0.17	300	Poor	Less constant back pain after 180 units return of condition, worse in 36 hr after medication stopped, better than acetylsalicylic acid
10	C. N. (No 09771) ambulatory	M	51	8	Moderate remission in part	Hospitalization with no benefit	Active exacerbation increased pain and marked functional symptoms	Decalcification of tarsal and carpal bones	1.57	1.63	300	Good	No benefit from cobra venom, unable to do without acetylsalicylic acid at any time
11	G. M. (No 170093)	F	62	7	Moderate progressive	Symptoms both knees and sold with moderate benefit	Active exacerbation with severe pain and arthritis	Decalcification of metacarpals and feet	1.53	1.42	300	Good	Increased pain during treatment, and joint motions more restricted
12	C. O. H. (No 34533)	F	37	10	Moderate slowly progressive remission in part with pregnancy	None	Active exacerbation 1 yr moderate pain	Narrowing of joint spaces some joint destruction in hands, wrists and feet	0.61	0.38	300	Good	Increased pain while taking cobra venom, local treatment of injection frequently requested acetylsalicylic acid for relief

Subjective Improvement

Three of the 12 patients (Cases 2, 4 and 9) experienced some degree of subjective improvement. In Case 2 the patient claimed 50 to 75 per cent relief, manifested by decrease in pain and stiffness, first noted after the administration of a total of 175 units. He considered the effect superior to that of acetylsalicylic acid. In Case 4 the patient admitted 25 to 50 per cent relief of pain, apparent after a total dose of 175 units, but stated that aspirin was equally effective. Both these patients were treated during exacerbations of the disease and had almost constant pain and stiffness. In Case 9, an ambulatory patient in a partial remission experienced about 50 per cent relief based on inconstancy rather than decreased intensity of pain after receiving 180 units. Acetylsalicylic acid was regarded by her as inferior. The prolonged analgesic effect attributed to cobra venom was not observed, since her symptoms increased within thirty-six hours after the drug was discontinued.

All nine of the remaining patients experienced either no relief or an actual increase in the amount of pain and stiffness, possibly owing to the withdrawal of acetylsalicylic acid. They invariably believed the latter to be a superior analgesic.

Objective Improvement

Reduction of articular swelling or effusion or increase in muscle strength or range of joint motion was not observed in a single individual. An attempt was made in Cases 1, 2, 3 and 4 to measure objectively the effect of cobra venom on pain threshold in order to note any correlation with subjective improvement. A modification⁸ of the method of Hardy, Wolff and Goodell⁹ was used, consisting essentially of determining the threshold for the pain produced by thermal radiation of the skin.* The relation between pain elicited in the skin by thermal radiation and that arising from a diseased joint is not established. However, the measurement employed offers the most satisfactory method available for obtaining objective evidence of reduced sensitivity to pain.

In Case 1, nine determinations were made before and during treatment. All results remained within the normal range expected for race and age. This agreed with the clinical response. One patient (Case 2), who derived the greatest benefit subjectively, showed an extremely high threshold of pain at first, but no change in eight subsequent tests during treatment. The lack of subjective relief in Case 3 coincided with the lack of alteration

of pain threshold even after a total dose of 375 units. Subjective improvement in Case 4 was first admitted after 175 units. However, it was not until a total of 440 units had been given that it became possible to discern an appreciable elevation in pain threshold as objective evidence of relative hypoactivity.

Although the results of this study indicated a slight correlation between subjective and objective findings, the number of patients was too small to permit definite conclusions.

Laboratory Studies

No striking effect on the sedimentation rate was noted. In one patient (Case 2) who showed subjective improvement the rate rose from 1.54 to 1.67 mm. per minute, whereas another (Case 12), who had increased symptoms during treatment, showed a fall in the sedimentation rate from 0.61 to 0.38 mm. There were no appreciable changes in erythrocyte and leukocyte counts or hemoglobin content. Urinalyses did not deviate from normal. Neither febrile nor antipyretic effects were observed as a result of the venom.

SUMMARY

The effects observed with large doses of cobra venom for the control of pain in rheumatoid arthritis were disappointing and contrary to previous reports. Three of 12 patients experienced subjective relief, estimated variably from 25 to 75 per cent. In no case was improvement complete, dramatic or lasting. There were no objective alterations. The only significant toxic effect was local reaction at the site of injection in 1 patient. Acetylsalicylic acid was considered to be as good or better as an analgesic by 10 of the 12 patients studied.

The results indicate that cobra venom is of no value for the relief of pain associated with rheumatoid arthritis.

METHYL SALICYLATE POISONING

A Report of Five Cases

CAPTAIN ROBERT A. MACCREADY, MC, AUS*

BOSTON

THE danger of poisoning by oil of wintergreen has not been sufficiently emphasized. It is commonly used in the home, and may be accidentally ingested by children, who, as Shipley¹ points out, may associate the pleasant aroma with wintergreen-flavored candy. It is therefore wise to continue the reporting of such cases. I present a brief summary of the cases reported to date, and 5 additional cases, 2 of which were seen by me.

Lawson and Kaiser² in 1937 tabulated 43 cases from the literature and added 1 of their own. In the same year Stevenson³ gathered 45 reported cases, 10 of which were not included in Lawson and Kaiser's summary, and added 3 of his own—making a total of 57. Not included by either author were 4 cases reported by Shipley¹ in 1933, and 1 case reported by Bowen, Roufa and Clinger⁴ in 1936. In 1938, Kane⁵ reported 2 cases, Eimas⁶ 1 case, and Baxter, Hartwell and Reck⁷ 2 cases. Donatelli and Abbate⁸ reported 1 case in 1939, Shurreff and Pearlman⁹ 2 cases in 1940, and Epstein and Work¹⁰ 1 case in 1942. To this final total of 71 reported cases are added the 5 additional cases described below.

Thirty seven of these 76 patients died. Twenty-three of the fatal cases occurred in children under five years of age. The smallest fatal doses were estimated at 4 cc. for a child one and a half years of age,² and 4 cc. for a two year-old child.³ A number of small children died from slightly larger doses. One death in a two-and-a-half-year old child following the external administration of methyl salicylate was reported by Lawson and Kaiser.² The smallest fatal dose reported in an adult was 6 cc.¹¹ The largest estimated doses followed by recovery were 30 cc. for a child two years of age, and 30 cc. for several adults.^{2,8} However, dosage reports, even as estimates, are obviously only partially reliable, particularly in small children.

The usual more severe course involves vomiting, hyperpnea, diaphoresis, extreme thirst, dehydration, stupor and convulsions. In the fatal cases death commonly occurs within twenty four hours. Kane⁵ reported a patient who died two and a quarter hours after ingestion of the poison. The commoner pathological findings observed at autopsy in cases of methyl salicylate poisoning^{11,12} include acute degenerative nephritis, edema and

fatty degeneration of the liver, congestion and edema of the lungs, acute gastritis and hyperplasia of the lymphoid structures in the intestinal tract, and small hemorrhages in the pericardial membrane and the pleurae and subdurally. Dodd, Minot and Arena¹³ have studied the altered physiology in salicylate poisoning in general, and have discussed treatment rationale, including the necessity for administering large amounts of fluid and combating acidosis.

The 5 additional cases are as follows:

CASE REPORTS

CASE 1. A 2 year old boy was brought to the office about 4 hours after having swallowed an estimated 15 cc of methyl salicylate, this was followed by vomiting and alternate periods of restlessness and mild stupor. The chief features on his arrival were marked perspiration, rapid breathing and pale mucous membranes. Vomiting was mechanically induced. Following this procedure, a Levin tube was introduced and the stomach was thoroughly irrigated with a dilute solution of sodium bicarbonate. A definite oil of wintergreen odor was obtained from the aspirated fluid. The lavage was continued for a long period of time, until finally no odor of the drug could be detected. The patient was then sent to the hospital with a guarded prognosis.

Treatment at the hospital consisted chiefly in forcing fluids by mouth, including dilute solutions of sodium bicarbonate. Significant laboratory findings were acetone, diacetic acid and a trace of albumin in the urine and a white cell count of 20,000. The child's symptoms and the urinary findings subsided fairly promptly. He was discharged home in good condition on the 3rd day.

CASE 2. A 55 year old man was seen about 6 hours after having ingested one tablespoonful (15 cc) of methyl salicylate for "heartburn." He was unaware of the toxicity of the drug for internal use. One hour after ingestion, the patient developed uninitus, "a full head" and numbness of the upper and lower extremities. Two hours later he became hot, perspired freely and breathed rapidly. Because of intractable gagging with attempted use of the nasal tube, an automatic lavage was employed by having the patient drink huge quantities of a dilute solution of sodium bicarbonate, with consequent induction of vomiting. A strong oil of wintergreen odor was present in the vomitus. The treatment was continued for an extended period of time, until finally no odor could be detected. After vomiting, the patient stated that he felt better immediately and that the numbness had greatly decreased. The patient had no sequelae except for a transitory albuminuria.

Two urine specimens produced slight reduction of Benedict's solution, but the patient failed to co-operate with requests for further checking. It therefore is not

*Epidemiologist, Massachusetts Department of Public Health (on leave of absence).

known whether the copper reduction was the result of the salicylate or of a mild underlying glycosuria.

CASE 3.* A 2-year-old girl was seen in her home about 6 hours after she had ingested methyl salicylate. An estimated ounce (30 cc.) was missing from a bottle containing synthetic oil of wintergreen, but some had been spilled. An oil-of-wintergreen odor was present on the child's breath. There were rapid breathing and restlessness. The child was hospitalized.

In the hospital, hyperpnea was marked, the pulse was rapid, and pallor was present. The patient's condition appeared to become serious, and she was alternately listless and restless. Treatment consisted chiefly in stomach lavage, sodium bicarbonate medication and repeated saline hypodermoclyses. The patient showed improvement after 15 hours of treatment, and was well enough to be discharged home on the 3rd day.

CASE 4† A child about 3 years old was seen in the accident room of the Cambridge City Hospital about ½ hour after the ingestion of oil of wintergreen. About one quarter of an ounce (7.5 cc.) was missing from the bottle, but some had been spilled. The patient vomited profusely, and further vomiting was then induced. As the patient did not appear ill, he was sent home without further treatment. About ½ hour later convulsions occurred, to which, however, the patient was said to be subject. Arrangements were made for immediate return to the hospital, but on arrival the patient was dead. Death had occurred within 2 hours after the taking of the poison.

CASE 5‡ A 48-year-old woman was admitted to the Cambridge City Hospital 2 hours after having taken one teaspoonful (4 cc.) of methyl salicylate by mistake. She had vomited shortly afterward, noted ringing of the ears and felt nauseated. On entry, the patient's stomach was lavaged, and later 2000 cc. of 5 per cent glucose solution was given by clysis. No further toxic symptoms developed. The urinary findings were negative except for an "orange" copper reduction, which could have been due to the glucose medication. The patient was discharged home recovered on the 7th day.

DISCUSSION

The toxicity of oil of wintergreen should be more widely appreciated. Its poisonous nature when ingested should be stressed in medical schools, and among physicians and the laity. Bottles containing methyl salicylate should bear poison labels and be kept safely out of reach of children.

*Reported through the courtesy of Dr. John J. McLaughlin of Albany, New York.

†Reported through the courtesy of Dr. Robert F. Ober, of Brookline, Massachusetts.

Cases 1, 2 and 5 suggest the value of prompt and thorough lavage. This procedure may very well have been the chief reason for the mild courses that followed. Lavage and the copious administration of parenteral fluids in Case 3 presumably aided in the recovery of this more seriously afflicted patient.

Treatment to rid the stomach of the poison must be adequate. Mere vomiting may induce a false sense of security. Indeed, more than one child has died after a parent has been told that its vomiting precluded the necessity for further treatment. Ordinary vomiting does not completely remove methyl salicylate from the stomach. Gastric lavage should be done when the patient is first seen, and should be prolonged until no trace of the drug odor is present in the washings. If the tube is not tolerated, an automatic lavage should be employed: that is the patient should be forced to drink huge quantities of water or of a dilute solution of sodium bicarbonate, with consequent induction of vomiting. To be adequate the process must be repeated again and again.

SUMMARY

The toxicity of methyl salicylate is emphasized, and proper treatment following its ingestion is discussed.

Five such cases of poisoning are reported.

MEDICAL PROGRESS

HEMATOLOGY*

WILLIAM DAMESHEK, M.D.†

BOSTON

DURING 1942, relatively little that is new or startling in the hematological field has occurred. Further developments with reference to the Rh factor and its relation to erythroblastosis foetalis have taken place; much has been written of transfusions, plasma and transfusion reactions; the hemolytic syndromes continue to occupy a prominent place; and the hemorrhagic states have received much attention. Leukemia remains as much of a problem as heretofore despite an initial flurry of enthusiasm for radio-phosphorus.

BLOOD CELLS

The matter of *elliptic erythrocytes* and *elliptocytosis* has been studied by Wyandt, Bancroft and Winship.¹ Eighty-six new cases in three large families of German extraction are reported. In all except 1 case, in which there was an associated spherocytosis, no anemia or other abnormality was present, and the condition was apparently without significance. All vertebrate animals with the exception of mammals have elliptic and nucleated red cells. The further exception to the latter statement is the camel, which has elliptic, non-nucleated red cells. It is probable that elliptocytosis is commoner than is generally recognized. This abnormality should not be confused with the elliptocytosis occurring in connection with the target cell and increased hypotonic resistance, noted chiefly in persons of Italian and Greek origin. There is a large group of syndromes affecting Mediterranean peoples, chiefly Italians, which is characterized in part by the presence of abnormally thin, hypotonically resistant target cells (so-called "leptocytes") and elliptocytes.² These disorders are inherited as a Mendelian dominant and vary in severity from the fatal Cooley's anemia to very mild conditions of no significance to the individual himself, but important from the hereditary standpoint.

The *target cell*, as noted in previous reviews, is assuming greater importance as it is realized that from the standpoint of thickness, three types of red cells can be discriminated: the normocyte, approx-

imately 2.0 microns thick; the spherocyte, 2.5 to 3.5 microns thick; and the leptocyte, approximately 1.5 to 1.7 microns thick. The thicker the red cell, the more fragile it is to hypotonic salt solutions. The leptocyte is thus the antithesis of the spherocyte. Of interest is the fact that the former cell is present in large numbers in sickle-cell anemia. It is possible that the target cell, the oval cell and the sickle cell—when they are inherited—are more or less related. The target cell may occur, as Bohrod³ has pointed out, shortly after hemorrhage; there it probably represents a relatively thin and somewhat younger red cell. To assume, as Bohrod does from the findings after hemorrhage, that the target cell is always simply a hyper-resistant young cell that appears in the blood following active bone-marrow regeneration seems illogical, since it is commonly found in persons without evidence either of blood loss or of increased blood destruction. In another paper, Bohrod⁴ points to an increasing resistance of the bowl-shaped target cell to dilute acetic acid.

Schleicher⁵ discusses at length the origin and nature of the *Cabot ring bodies* in erythrocytes. Although most authorities have considered them to be of nuclear origin, Schleicher presents evidence that they are actually the expression of a denatured or colloid protein connected with the nucleus and produced by the activity of a lysin on the lipoprotein constituents of the red cell.

The exact nature of the *eosinophil* remains obscure. It is certainly a granulocyte and thus a bone-marrow cell. However, its behavior with respect to pathologic processes differs strikingly from that of the neutrophilic granulocyte. Thus in acute pyogenic infections, with a sharp increase in polymorphonuclear neutrophils, the eosinophils drop out of the picture, whereas with subsidence of the infection they increase in number. Thus the eosinophil seems to have a reciprocal relation to the neutrophil. Why it becomes increased in allergic conditions and in such widely separated entities as parasitic infestation and periarteritis nodosa is not known. The stimulus that provokes the production and delivery of eosinophils to various parts of the body, and thus eosinophilia, is as yet obscure. An unusual, although by now well-documented, type of eosinophilia is that described by Loeffler of Switzerland in 1936 and often known as *Loef-*

*Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual*, Vol. III, 1942 (Springfield, Illinois: Charles C. Thomas Company, 1942, \$5.00).

fler's syndrome. This is characterized by a transient and rapidly shifting infiltration of the lungs, and is accompanied by relatively few symptoms, indicating a mild infectious process. Eosinophilia of 15 to 35 per cent, occasionally higher, is present. Neither the nature of the infection nor the cause of the eosinophilia has been determined. Elsom and Ingelfinger⁶ report a probably related, if not identical, entity in 2 cases of eosinophilia and pneumonitis in chronic brucellosis. Both cases showed well-defined eosinophilia up to 42 per cent, peculiar pulmonary lesions and rather definite evidence of brucellosis. The cases known as Loeffler's syndrome were not studied for the question of undulant fever, and it is possible that both Elsom and Ingelfinger's cases and those of Loeffler and others may be peculiar examples of brucellosis with involvement of the lungs and with eosinophilia.

Infectious mononucleosis continues to present interesting diagnostic possibilities. It is a common infectious disease, and despite continued publicity is still frequently mistaken for other conditions. Mild fever in a young adult, particularly if he is a student or in some branch of the medical profession, should make one at least suspect the possibility of the disease. Severe headache ushers in most cases and may be mistaken for encephalitis, encephalomyelitis or kindred affections. The spinal fluid in these cases may show lymphocytosis and thus lead to the diagnosis of choriomeningitis or aseptic lymphocytic meningitis. Although the spinal-fluid lymphocytosis is generally regarded as a complication of the disease, it is simply indicative of the widespread lymphoid reaction which may result in perivascular collections of lymphocytes in the brain, and in serous meningitis. Zohman and Silverman⁷ report a case with diffuse lower motor-neurone disease. The throat lesions, although mild in most cases, may be unusually severe in others and accompanied by marked swelling of the neck. If this is so, there is usually a complicating Vincent's infection for which a small dose of neoarsphenamine may be given intravenously. Rarely, the throat reaction may be due to a complicating pneumococcal infection that will respond readily to one of the sulfonamide drugs.

The blood picture shows a well-marked lymphocytosis with the presence of all varieties of lymphocytes, frequently bizarre in shape, size and staining characteristics. The absence of well-defined anemia and of reduction in platelets are two important criteria that should immediately rule out the diagnosis of acute leukemia. However, every rule has its exception. Thus, every so often one sees a case of thrombocytopenic purpura with well-defined lymphocytosis. The diag-

nosis of acute lymphatic leukemia is naturally made, although this can generally be ruled out when the great variability in lymphocytes is noted. In acute leukemia a monotonous blood picture is present, most of the cells being lymphoblasts. As Minot pointed out several years ago, many cases of idiopathic thrombocytopenic purpura present lymphocytosis in which some relatively young forms are rather common. That infectious mononucleosis will occasionally, particularly when splenomegaly is present, result in thrombocytopenic purpura is not well known: I have seen 2 such cases and Brooks⁸ reports another.

A pink macular rash which fades readily on pressure is found occasionally. The mesenteric adenitis with its resultant abdominal pain may result in the diagnosis of acute appendicitis, especially since the leukocyte count is usually elevated. Straus⁹ reports a case in which, although the white-cell count was low, — as it is in about 10 per cent of cases of infectious mononucleosis, — the diagnosis of acute appendicitis was made and operation performed. The appendix was the site of an atypical hyperplasia of the lymphoid tissue, which appeared identical with lesions previously described by Gall in enlarged lymph nodes. It is thus a good rule to consider the diagnosis of infectious mononucleosis in every febrile condition in a youngster or a young adult. Cases in very young children and in people above the age of thirty are unusual. The heterophil agglutination test, using sheep's red cells, is an important diagnostic criterion of the disease. It is positive in about 75 per cent of the cases. Why an antibody is produced that has the specific property of agglutinating sheep's red cells has not been determined, nor has any real advance been made in discovering the infectious agent. A virus etiology has naturally been suggested, and experiments indicating this as a possibility have been recorded by Wising¹⁰ and by van den Berghe and Liessens.¹¹ These investigators introduced glands or blood from patients with the disease into monkeys and produced an infection with suggestive clinical and hematologic features.

Therapeutically, no real progress has been made. As noted above, a complicating Vincent's infection of throat or gums may indicate the use of neoarsphenamine, and sulfathiazole may be used with a complicating coccal organism. I have failed to find any value, however, in the routine use of the sulfonamide drugs, although Hoffman, Lees and Comroe¹² state that sulfathiazole appears to be of definite value in shortening the symptomatic stage of the disease. Lassen and Thomsen¹³ claim benefit from the use of specific convalescent serum in doses of 60 to 300 cc. intravenously. This method probably deserves greater attention in this country

than it has heretofore received, although it must be conceded that most cases are very mild and require only symptomatic treatment. The best thing about the condition is, however, its 100 per cent recovery rate.

In the last few years, a new infection resulting in such phenomena as generalized lymphadenopathy and splenomegaly and caused by the *Histoplasma capsulatum* (Darling) has been described. Wright and Hachtel¹⁴ illustrate a case report of histoplasmosis with some excellent photographs of the organism both in cultures and in tissues. The histoplasmosis is a fungus that has two forms. One is yeastlike and occurs in the blood and reticuloendothelial cells, whereas the other, a mycelial form, develops outside the body in cultures held at room temperature. The yeastlike forms grow only on blood or serum agar at 37°C.

Only about 35 cases have thus far been reported. The symptoms are variable, with irregular fever, lymphadenopathy and splenomegaly outstanding. There may be a moderate normocytic anemia, and leukopenia is usual. As Reid, Scherer, Herbut and Irving¹⁵ point out in a case report, the parasites may be present within the blood cells and recognizable by ordinary blood smears. Sternal puncture in their case showed numerous monocytes and neutrophils containing inclusions resembling superficially Leishman-Donovan bodies. Blood culture is frequently positive, the organism growing out readily after several days either at room or incubator temperature. The disease is very serious and is often but not necessarily fatal. Therapy has not been successful, although antimony has been thought to be of some value.

Miscellaneous

An experimental study which may be of some clinical significance is that of Nettleship,¹⁶ in which heterologous bone-marrow antibodies were produced and injected into the donor animal. An extract of rabbit bone marrow was repeatedly injected into guinea pigs, following which the animals were bled. The guinea-pig serum, presumably containing bone-marrow antibodies, was injected into rabbits. A single large dose produced an indiscriminate necrosis of all the bone-marrow elements, the blood showing leukopenia and anemia. Repeated small doses caused fibrosis of the marrow.

Dameshek and Wolfson¹⁷ direct attention to the possible beneficial effects of the sulfonamide drugs in combating agranulocytosis. Because patients with agranulocytosis do not die of the reduction in granulocytes per se but rather of the resulting secondary sepsis, it was thought that the sulfonamides might be useful in combating the sepsis, the patient's bone marrow meanwhile having an oppor-

tunity to recover. Dramatic recoveries occurred in 2 very severe cases of aminopyrine agranulocytosis in which full doses of sulfathiazole were given. It is worth while remembering that the sulfonamides act by bacteriostasis and may be given with impunity in conditions with marked leukopenia.

With respect to the bone marrow, sternal puncture as a diagnostic help becomes ever more popular. As Mendell, Meranze and Meranze¹⁸ report, it is virtually diagnostic in acute leukemia, aleukemic leukemia, multiple myeloma, leishmaniasis, malaria and Gaucher's disease. I believe that when taken in conjunction with the blood picture the bone-marrow biopsy is all important in the study of cases of obscure or refractory anemia, and in anemias accompanied with increased hemolysis. Simple puncture is usually satisfactory, and in any event can always be done as a preliminary method. It is only occasionally necessary to resort to trephine biopsy of the sternum, a measure that becomes of value in assessing the general architecture of the marrow tissues, as in aplasia, fibrosis or certain cases with neoplastic infiltration. Shapiro and Bassen¹⁹ report their methods and the results obtained in studying the sternal marrow during the first week of life. They found that the formation of the red cells becomes suddenly curtailed during this period, perhaps because of the better oxygenation present in the outside world.

The blood volume in normal infants and children has been studied by Brines, Gibson and Kunkel,²⁰ using the dye Evans blue and a photoelectric colorimeter. The total volume, about 300 cc. at birth, doubles during the first year of life, and thereafter increases until puberty, when it is about 2500 cc. Both plasma and total volume are more closely related to physical size than to age, and may thus be predicted on the basis of the child's height, weight or surface area to a degree of accuracy sufficient for practical purposes. Some interesting studies on the response of normal subjects to acute blood loss have been made by Ebert, Stead and Gibson.²¹ The blood loss was observed under controlled conditions in 6 subjects from whom 760 to 1220 cc. of blood was withdrawn. The decrease in blood volume by hemorrhage was compensated in two ways: by vasoconstriction and by the addition of fluid to the blood stream. The change in hematocrit percentage accurately reflected the direction of the changes in the plasma volume in these experiments. Thus the continued increase in plasma volume was not well shown by a decrease in protein concentration but by a steady fall in the hematocrit reading, since the red-cell volumes remained relatively constant during a period of three days. These findings are important from the standpoint of studying cases of severe

blood loss with or without accompanying shock. The production, utilization and interrelation of hemoglobin and plasma proteins are discussed by Whipple²² in a review of the fundamental work which has been carried on for years in the famous dog colony and laboratories of the University of Rochester Medical School.

BLOOD TRANSFUSIONS AND BLOOD GROUPS

Owing of course to the exigencies of war, the transfusion of blood and plasma has assumed tremendous importance. By now everyone is familiar with the life-saving qualities of plasma in traumatic, hemorrhagic and surgical shock. Plasma, replacing as it does the fluid lost from the circulating blood, is an urgent necessity. Numerous methods have been published for preparing, storing, freezing, drying and administering plasma. In a series of articles, Strumia, McGraw and Reichel^{23, 24} give detailed directions for its preparation and preservation. These writers strongly advocate centrifugation of the blood to increase the plasma yield, and storage of the plasma in a frozen state. They claim that the latter procedure reduces infection to a minimum, and that this possibility may be still further reduced by collecting the plasma from the whole blood within twenty-four to forty-eight hours after its removal. In their fourth paper, the preparation of dried plasma is considered. The latter is of special value because it permits safe and prolonged storage and transportation under adverse conditions, and because the plasma may be reconstituted in a concentrated form for such conditions as edema of the brain. The methods developed by Strumia et al. have been widely utilized.

At the Army and Navy Blood Plasma Division in Washington, headed by Commander Newhouser^{*} of the Navy and Lieutenant Colonel Kendrick of the Army, plasma is stored in liquid form (with added Merthiolate) or kept frozen. Both the liquid and the frozen plasma are shipped throughout the country for use at various Army and Navy posts. Dry plasma, which is prepared by pharmaceutical houses from part of the donated blood, is used only for shipment abroad. Both liquid and frozen plasma have been found eminently satisfactory. Liquid plasma prepared by a *closed method with scrupulously aseptic technic* has been stored for at least twelve months at room temperature. When thus carefully handled, it not only remains free from bacterial contamination but is satisfactory for immediate use in shock. Furthermore, it does not require melting from the

frozen state nor reconstituting from the dried product.

Novak²⁵ recommends the use of one of the sulfonamides, preferably sodium sulfathiazole, in the preservation of blood plasma in a liquid state. A solution of 1.5 gm. of sodium citrate and 1 gm. of sodium sulfathiazole in 50 cc. of normal saline is used for 450 cc. of blood, giving a concentration of sulfonamide of 0.2 per cent. This method has been criticized by some and is not generally accepted.

Crosbie and Scarborough²⁶ present a series of studies on stored blood, which deal with such matters as the fate of the red cells, leukocytes and platelets, together with prothrombin content, coagulation time and so forth. These factors are also considered by Strumia and McGraw.²⁷ It is apparent that the drying of plasma results in the loss of almost all the prothrombin and of a portion of the complement present in liquid plasma. Since complement may be of value in combating infection, the use of dried plasma alone, as in burn cases, may not be completely desirable.

Work on the preparation of albumin from human and bovine blood has been vigorously pursued. From the standpoint of osmotic pressure and the retention of fluids within the vascular tree, albumin is of far greater importance than serum globulin. Thus, Newhouser and Lozner²⁸ have reported that 25 gm. of human albumin is osmotically equivalent to 500 cc. of citrated plasma, provided the patient is normally hydrated. It may be given in a small volume (100 cc.) of solution, and has a greater plasma diluting effect than twice the ordinary 250-cc. unit of plasma. This material, one of the chief advantages of which is its small bulk, is now being packaged for use in the Navy. It is chiefly of value as an emergency first-aid measure and its use has thus far been circumscribed by numerous precautions. At present, it cannot replace whole plasma.

A community method for the collection, preservation and distribution of plasma has been described by Gottlieb and Clapperton.²⁹ The existing fourteen community hospitals centering about the Central Maine General Hospital at Lewiston are utilized. All the bottles, apparatus and so on are prepared at the central hospital. In the community hospitals, blood is drawn from volunteer donors and is shipped to the central hospital, where it is processed. Part of the plasma is left in a large refrigeration unit at Lewiston, the remainder being returned to the community hospitals. In the event of disaster, the stock of plasma at the central station can be made immediately available for any of the smaller hospitals.

*I am indebted to Commander L. R. Newhouser (MC), U.S.N., for his kindness in verifying the statements relating to the Navy work with blood plasma and albumin.

All the bottles, apparatus and so on are prepared at the central hospital.

The question of the rate of hemoglobin regeneration in blood donors has been studied by Fowler and Barer³⁰ who found that the average time required to replace 550 cc. of blood was 49.6 days. Some subjects, on the other hand, required three months. With iron therapy, the average recovery time was shortened to 35.2 days. Fowler and Barer suggest that unless hemoglobin levels are regularly determined, an interval of three months between blood donations should be allowed.

The infusion of blood and other fluids into the bone marrow has assumed some importance, since the sternal-marrow space is almost always readily available, at least in adults and older children, whereas veins may at times be inaccessible. Tocantins and his co-workers¹¹ have demonstrated that substances injected into the bone-marrow cavity are immediately taken up into the venous circulation. The method is particularly applicable in infants and in patients with collapsed veins, as in shock, and when veins are completely inaccessible, as in patients with extensive burns. In infancy, below the age of two, the needle is introduced into either the upper end of the tibia or the lower end of the femur. Fluids, including blood, are introduced either by gravity, or by positive pressure if more speed is desired. For further details of the techniques involved, the original papers should be consulted. Tocantins has recommended a special double needle. By the use of a simple sternal-puncture needle,* however, Doud and Tysell³² administered 9025 cc. of whole citrated blood and 13,950 cc. of fluids to a patient with uncontrollable hemorrhage from the bowel due to ulcerative colitis. The needle remained *in situ* for several days at a time without evidence of infection or other complication. When blood or fluids were not being administered, the needle stylet was replaced. In this case, the procedure seemed definitely lifesaving.

There is some controversy regarding the use of so called "universal donors" (Group O). Although most authorities now believe that the blood of these donors, because of its content of anti-A and anti-B agglutinins, is inadvisable for use in Group A, B and AB recipients, this is contradicted by others, for example Rosenthal and Vogel.³³ An analysis by these investigators of 819 transfusions with universal donors has shown that such transfusions are not followed by any greater number of reactions than are those with homologous blood. They believe that the universal donor is both reliable and safe for citrate transfusions in emergen-

cies, either in civil practice or in the armed forces. My own experience indicates that in severe anemia, and particularly in hemolytic anemia, it is unwise to use anything but homologous donors. The agglutinin content of the universal donor's blood plasma, although safe enough in ordinary cases, may be high relative to the cells of severely anemic blood, more particularly when spherocytosis is present. Furthermore, in hemolytic cases the possibility of an isohemolysin or atypical intragroup agglutinin is always present.

Hemolytic reactions following transfusions of blood of the homologous group, with particular reference to the Rh factor, are described by Wiener.¹¹ It is possible to immunize an individual of the same blood group but who is Rh- with Rh+ blood, with the result that he develops an anti Rh agglutinin. When another transfusion of Rh+ blood is then given, agglutination of red cells takes place within the patient's circulation, with a resultant hemolytic reaction. Wiener advocates that whenever possible, homologous Rh blood be used in repeated transfusions. A safe universal donor, according to this author, is one of Group O, Rh-, with a low titer of isoagglutinins in his serum. To guard against the possibility of an atypical hemolysin or agglutinin, it is necessary to perform careful compatibility tests when repeated transfusions are given. These are done by the Landsteiner-Levine test-tube technique, in which 1 drop of 2 per cent red-cell suspension, 1 drop of serum and 1 drop of saline are incubated at 37° C. for half an hour, following which the mixture is examined both macroscopically and microscopically for agglutination. An ingenious method of utilizing Group O blood for universal-donor transfusions is the addition to the drawn blood of A and B substances, as developed by Witebsky and his co-workers. These substances, carbohydrate-like in nature, possess the properties of the A and B agglutinogens and therefore absorb or neutralize anti-A and anti-B agglutinins normally present in Group O plasma. A solution containing the A and B substances is being prepared by a pharmaceutical house for clinical use. Further investigations by Witebsky and Klendshoj³⁵ have resulted in the isolation of an O specific substance from gastric juice. This gives additional evidence of the presence of an O agglutinin, although usually the dictum has been that no such substance is present, and that Group O cells are devoid of both A and B substances.

PERNICIOUS ANEMIA AND RELATED STATES

Pathogenetic Mechanisms

The vexing problem regarding the site of origin of Castle's intrinsic factor has been investigated in

*Manufactured by the Becton-Dickinson Company, Rutherford, New Jersey, or the Hub Needle Company, Boston

the pig by Meulengracht and more recently in the human being by Fox and Castle.³⁶ Meulengracht assumed that of the various available animals for study the stomach most closely comparable to the human one was that of the pig. He found that in this animal the region of the pylorus (pyloric gland organ) was hematopoietically active, whereas the fundic portion was inactive. In human pernicious anemia, on the other hand, it is the fundic glands that are regularly involved, the pyloric portion remaining histologically normal. Meulengracht then formed the rather striking hypothesis that the fundus acts simply as an initiator or pacemaker of the pyloric-gland region, and that in the absence of this initiator there is no secretion of intrinsic factor. However, as Fox and Castle point out, these pieces of evidence become contradictory "only when conclusions which undoubtedly obtain for the hog are directly translated to man." These investigators demonstrated that extracts made from human stomachs showed very little if any activity in the pyloric region, although marked activity in the fundic regions was present. Thus there is a direct correspondence of the histologic lesions of the stomach of pernicious anemia with the physiologic experiments carried out with human material.

The neurologic lesions of pernicious anemia are often out of all proportion to the extent of the anemia. Conversely, many classic cases with outspoken anemia have minimal neurologic disturbances. This dissociation between the hematologic and neurologic changes has led many investigators to speculate that they may be due to different types of deficiency. Wintrobe and his co-workers have for many years tried unsuccessfully to reproduce in animals the hematologic changes of pernicious anemia. However, in the course of their investigations, the neurologic manifestations have been faithfully reproduced by the use of a diet deficient in various fractions of the B complex, but in which thiamin, riboflavin and nicotinic acid were supplied.³⁷ Wintrobe's investigations have cast doubt on thiamin as the anti-neuritic vitamin. In these studies, the neurologic lesions were completely prevented by the use of potent liver-extract preparations given orally and by the use of pyridoxin (B₆), pantothenic acid and perhaps choline. Is the deficiency of these substances then the cause of the neurologic lesions of pernicious anemia? This question and the problem of the exact relation of these studies in swine to human disease remain to be answered. The continued failure of many different groups of investigators to reproduce in animals the typical hematologic disturbances of pernicious anemia suggests either that a deficiency state may produce results in man different from those in experimental animals, or that the concept of the intrinsic factor, its forma-

tion, elaboration and so forth is only partially explanatory of the pathogenesis of the disease.

Certain cases of pregnancy are associated with the typical blood changes of pernicious anemia. The gastric analysis may show free hydrochloric acid, and complete recovery may occur after a period of liver-extract therapy. Segerdahl³⁸ studied the sternal marrow of several cases and found megaloblastic and leukocytic changes as seen in typical pernicious anemia. There can thus be no doubt that a liver-extract deficiency accounts for the development of these cases. Whether this is dietary in origin or due to a large abstraction of material from the mother by the fetus is not clear. Liver extract alone is often only very slowly curative, and transfusions are also required in a few cases.

Not all macrocytic anemia is pernicious anemia. Thus, the macrocytic anemia of hepatic disease, more particularly cirrhosis, does not necessarily indicate that there is a deficiency of the liver-extract principle. In the experience of practically all investigators, purified liver extract produces little if any change in the blood picture. Furthermore, the demonstration by Schiff and his co-workers³⁹ some years ago that the specific antianemic substance is present in human livers with cirrhosis indicates that the two macrocytic anemias are of entirely different origins. Rarely, pernicious anemia with the typical bone-marrow findings and response to liver extract is coexistent with cirrhosis. Ratnoff and Patek⁴⁰ found 2 such patients in their series of 386 well-studied cases.

The blood picture of sprue, both tropical and nontropical, differs in several small respects from that of Addisonian pernicious anemia. The red cells are regularly macrocytic without much change in size or shape, the platelets may be normal, the bilirubin content of the blood is usually low, and so on. Furthermore, free hydrochloric acid is present in the gastric juice of most patients; the bone marrow is hardly megaloblastic in character; there are severe intestinal disturbances, often associated with hypocalcemia; the sugar-tolerance curve is flat; and the response to liver extract is either sluggish or nil.

Hanes⁴¹ describes several cases of the sprue syndrome (including celiac disease and sprue), and Molina⁴² describes 100 cases of tropical sprue. Extreme muscular wasting was striking in Molina's cases. Direct examination of the gastric and rectal mucosa showed changes similar to those seen in the tongue and pointed to faulty absorption of food products by the bowel. Although a deficiency state is undeniable, the fundamental cause of the intestinal malabsorption is still obscure. The concept advanced by Castle and Rhoads in 1935 that a deficiency state similar to if

not identical with pernicious anemia is present is questioned by Molina, who points to the severe intestinal dysfunction as the most prominent feature of the disease. This may be due to the continued use of fried or greasy food and of cereals, with resultant irritability of the bowel. The x-ray findings in the small intestine in sprue and in vitamin B deficiency are beautifully described by Golden.⁴³ A deficiency pattern, centering about changes in the small bowel, is pictured in which the prominent features are hypermotility and later hypomotility, abnormal segmentation, "scattering effect," gas and fluid levels, changes in the mucosal membrane and so forth. These changes frequently respond strikingly to liver-extract or yeast therapy. Further studies along the same lines are presented by Lepore and Golden.⁴⁴

Treatment

A number of experimental studies have recently appeared dealing with further attempts at using the experimental animal for the assay of liver-extract preparations. Several of these studies have dealt with the supposedly megaloblastic, liver-extract-deficient type of hematopoiesis in the embryo. Thus, Stasney and Higgins several years ago used the newborn rat, and more recently Stasney and Burns⁴⁵ utilized young opossums, which are conveniently situated (like kangaroo young) in a pouch and yet are embryonic. The changes in the size of the red cells after administration of liver extract has been utilized by these observers as a criterion of response to therapy. Jones⁴⁶ used pregnant rats from which eleven-day embryos were obtained. Blood smears of the yolk sac of the embryo were stained and the red-cell and nuclear diameters were counted both in control animals and in those in which the mothers had been given either gastric or liver-extract preparations. The assumption was of course made that the erythrocyte-maturing principle had passed across the placental membrane. Jones demonstrated a definite effect on erythropoiesis in the embryo as indicated by a reduction in the mean cell and nuclear diameters of the primitive erythroblasts. Ventriculin concentrate was most effective. The results of both Stasney and his collaborators and of Jones have been questioned by Last and Hays,⁴⁷ who found that statistical analysis of the data indicated that the responses in the treated animals were within the range of biologic variation. They concluded that neither opossum nor rat embryos should be used in the bioassay of antianemia preparations. The mildly polemic postscripts of Jones *vs.* Last and *vice versa* make interesting reading. Further studies by Hays, Last and Koch⁴⁸ indicate that erythropoiesis in the three-to-seven-day-old chick embryo also cannot be utilized for assay purposes.

For the present, one must still be content with human assay material, which is, however, scarce and often difficult to control.

The striking changes in the bone marrow from a megaloblastic picture to one that is normal (normoblastic) in type are further discussed by Davidson, Davis and Innes.⁴⁹ Dameshek and Valentine⁵⁰ several years ago investigated the changes that occur and interpreted them as a change from a liver-extract-deficient megaloblastic erythropoiesis to a liver-extract-satisfied normoblastic type. Davidson et al. claim that the megaloblast is not specific for liver-extract deficiency and interpret the rapid changes after treatment as indicative of a normal type of erythropoiesis. My own interpretation of the same phenomena, which is radically different, seems borne out by bone-marrow studies in various other deficiency syndromes.

The clinical use of liver-extract therapy is considered in a group of articles by Evans and Jordan,⁵¹ Strauss, Patek, Pohle, Fox and Burchenal,⁵² and Seymour, Heinle and Miller.⁵³ Evans and Jordan found that a highly concentrated liver-extract preparation (Reticulogen) was far more effective than less concentrated extracts, not only in controlling the blood counts but in improving the neurologic lesions. Strauss and his co-workers, after an initial bias for the very crude extracts, have now adopted a uniform maintenance dose of 15 U.S.P. units of purified liver extract every four weeks. During eighteen months of this regimen no subjective or objective relapses in the blood, gastrointestinal or nervous system were observed. Seymour et al. found that patients differed in their ability to store large quantities of liver extract given in relapse. This difference probably depends to great extent on the degree of intrinsic factor lack and to some extent on the diet (that is, the potency of the extrinsic factor).

(To be concluded)

**CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITAL**

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, MD, *Editor*

CASE 29051

A seventy five year old woman was referred to this hospital because of difficulty in swallowing, epigastric discomfort and nervousness.

Twenty five years before entry, the patient felt a nodule about the size of a walnut on the left side of the neck. Her physician said that her basal metabolic rate was normal and that the nodule had no significance. Thirteen years later, because of a "nervous spell" characterized by headaches, nervousness and mental uneasiness, she consulted a local clinic. At that time there was no sweating, palpitation, tremor or diarrhea and the neck nodule had not increased in size. At this clinic, because of an apparently normal x ray film of the chest and an unremarkable basal metabolic rate, the patient was told that the neck nodule would never bother her. Five months before entry she noticed that food seemed to stick in her throat, and several days later her neck began to swell. Six weeks before entry, her physician advised an operation on the "goiter," and four weeks later she entered a community hospital. There an x ray film of the upper chest and neck revealed an "adenomatous goiter" that extended 4 to 5 cm below the clavicles, the trachea was deviated to the right. The blood cholesterol was 215 mg per 100 cc, and the basal metabolic rate was -10 per cent. She was treated with a course of x ray radiation to the neck in five divided doses, following which her neck became swollen. She was referred to this hospital for further care. She had never noticed exophthalmos, palpitation, sweating, tremor, diarrhea, jaundice, abdominal pain or tarry, bloody or choleric stools.

The family and past histories were noncontributory.

Physical examination revealed a dyspneic and orthopneic woman who did not appear to be in great distress. The left pupil was larger than the right, but both were round and reacted to light and accommodation. The thyroid gland was enlarged on both sides, particularly on the left, and extended beneath the sternum; it seemed quite firm, but no discrete nodules were felt and no bruit was audible. The external jugular veins

were prominent over it, and the trachea was deviated to the right. The heart was not enlarged, and the sounds were of good quality, occasional extrasystoles occurred, but no murmurs were audible. The examination of the lungs and abdomen was negative. There was fixation of the left vocal cord, and some compression of the infraglottic airway.

The blood pressure was 170 systolic, 90 diastolic. The temperature was 97°F, the pulse 89, and the respirations 24.

Examination of the blood revealed a hemoglobin of 80 per cent and a white cell count of 7700. The urine was acid in reaction and gave a "green" sugar test and a + test for albumin, the sediment contained 15 to 20 white cells and 1 or 2 red cells per high power field. The sugar test was "blue" on two subsequent examinations.

An x ray film of the chest, including the neck, demonstrated a large soft tissue mass occupying the position of the thyroid gland, measuring 10.5 cm across and extending subcutaneously to the level of the aortic arch. The mass was of considerable density. The chest was narrowed laterally. The diaphragm was low in position and showed limited motion on both sides. The lung fields were unusually bright, and there was an increase in the markings. The heart was small. An electrocardiogram demonstrated a normal sinus rhythm of 90. The PR interval was 0.14 second, the T wave was isoelectric in Leads 1, 2 and 3, and T₄ was shallow, the ST segment in Leads 2 and 3 was slightly depressed.

An operation was performed on the fifth hospital day.

DIFFERENTIAL DIAGNOSIS

DR SAUL HERTZ: I should like to emphasize that the patient found the nodule and went to her physician. I think the lump that the patient finds is probably more significant than the one that the doctor finds. For a patient to remember twenty five years back is an important point in the diagnostic elements of the case. The physical examination later describes a uniform enlargement in the region of the thyroid gland and that is why I am making this point about the patient's description of the nodule. Apparently the physicians in the clinic that the patient visited found the same thing and confirmed the patient's finding.

We are not certain whether it was truly the thyroid gland that was involved. The fact that she was treated with x ray radiation seems to indicate that her physicians were thinking of lymphoma, and gave a therapeutic x ray trial, apparently without a biopsy. The swelling after x ray therapy might point to some form of lymphoma,

but I do not believe that is a significant point in the differential diagnosis; however, the lack of response is.

We are left, then, with an old lady with a twenty-five-year-old mass in her neck, which apparently had undergone certain changes in the previous twelve years, particularly in the previous five or six months. On physical examination, dyspnea and orthopnea were found in a person who was described, nevertheless, as not being in great distress. Orthopnea may not be distressing for some people, but I am sure it would be for me. One would like to know whether they thought the orthopnea was associated with definite stridor. That would be important in ascertaining the degree of compression of the trachea and would help quite a bit.

The dilatation of the pupil on the left indicates stimulation of the cervical sympathetic nerves on that side. It seems to indicate disorder in the left lobe of the thyroid gland, if it was the thyroid gland, compressing the recurrent laryngeal nerve and causing paralysis of it. We are told later that the vocal cord on that side did not move.

The description of the gland is of value in trying to diagnose this case. I should like to be sure that it was uniformly enlarged and non-nodular, because it makes all the difference in the world in defining this case as cancer of the thyroid or chronic thyroiditis. A picture similar to this can be produced by the invasive type of chronic thyroiditis, Riedel's struma, causing involvement of the recurrent laryngeal and sympathetic nerves. Apparently there was also some interference with venous circulation, pointing to an upper mediastinal syndrome, conceivably on a lymphomatous basis.

The deviation of the trachea to the right is significant because it tends to indicate that the disease was well defined on the left and possibly that the old nodule had something to do with the recent disorder. In the past history of cases of thyroid cancer, the finding of pre-existing goiter is frequent.

The invasive character of the mass in the neck is in favor of either carcinoma or chronic thyroiditis; although a nontoxic goiter that has expanded because of hemorrhage or cystic degeneration may cause considerable pressure on the recurrent laryngeal nerve and give a picture similar to this, I think it unlikely.

At the age of seventy-five, with a nodule of many years' duration, which I am taking seriously, carcinoma has to be considered as the first possibility. However, the fact that the thyroid gland is described as uniform makes me lean toward chronic thyroiditis. I think the x-ray film will be helpful and should like to see it at this point.

DR. LAURENCE L. ROBBINS: This is the mass that lies in the region of the thyroid gland. It is practically symmetrical on both sides, and extends down to the level of the aortic arch. I notice that the report said that the mass was of considerable density. They probably meant ordinary soft-tissue density. I do not believe that there are areas of calcification within the mass; there is a fleck here but it is probably pleural or in the lung. The remainder of the chest shows considerable emphysema and questionable early fibrosis.

DR. HERTZ: The x-ray film suggests that the mass was uniform. I cannot remember having seen a case of chronic thyroiditis in which the mass extended into the thorax to this extent, and I tend to rule it out on that basis. That brings me down to one diagnosis—thyroid carcinoma in a long-existing nodular goiter. There are a few rare conditions that should be considered. Could this be something other than the thyroid gland, even though the x-ray man and the clinical examiners indicated that the thyroid gland was involved, and the early story centers around the thyroid nodule? Perhaps the unusual turned up here, and I should like to put on record the possibility of carcinoma of the esophagus or bronchus, since the patient complained of dyspnea. But I doubt whether these would cause metastasis to the mediastinum of this type without more characteristic glandular metastasis in the neck. If this was an extrathyroid cancer it manifested itself in an odd way. There is also a bare but unlikely possibility that this was a benign tumor, a nontoxic nodular goiter.

CLINICAL DIAGNOSES

Tracheal obstruction, due to colloid goiter.
Arteriosclerotic heart disease.

DR. HERTZ'S DIAGNOSIS

Carcinoma of thyroid.

ANATOMICAL DIAGNOSES

Malignant lymphoma, stem-cell type, of cervical and mediastinal nodes.
Nodular colloid goiter.
Tracheotomy.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: Shortly after entering the hospital the patient developed symptoms of marked respiratory obstruction; it was believed that emergency relief was required so a tracheotomy was done and a small portion of the mass was removed, in part as a biopsy and in part with the hope of relieving some of the tracheal obstruction. Microscopic examination showed a benign colloid goiter. Following the operation, the patient ex-

perienched little relief and had successive episodes of severe tracheal obstruction, some of which could be relieved by aspiration of the tracheal secretions; she eventually died with respiratory obstruction.

The autopsy showed a large tumor mass in the upper mediastinum and lower neck that completely encircled the thyroid gland but did not involve it. This turned out to be a malignant lymphoma of the undifferentiated or stem-cell type. The thyroid gland was only slightly enlarged, and we did not find any particular area that we were convinced was the mass the patient had noted for twenty-five years. That must have been lost in the general tumor mass.

DR. HERTZ: I want to emphasize one point. We are often asked what to do about a single nodular goiter. Frequently the history is given that the patient has had such a mass for twenty or more years. Here is a case in point. How much can we trust the history in dealing with nontoxic nodular goiter? It is of no great diagnostic value to us unless we have seen the nodule ourselves and have made up our minds that it did lie within the thyroid gland. But nothing is said in the record whether the mass rose and fell after deglutition, an observation that should be recorded in any description of a case where the possibility of thyroid disease is considered.

DR. MALLORY: I think that all the examiners felt quite sure that it was thyroid gland, including the surgeon who operated on her, who still thought the obstruction was due to the goiter when the operation was over.

CASE 29052

PRESENTATION OF CASE

A fifty-nine-year-old widowed housekeeper entered the hospital because of a vague epigastric distress that often interfered with her sleep.

During most of her adult life the patient had, like her mother before her, suffered with brief attacks of "biliousness" that occurred once or twice each year and spontaneously disappeared. Occasionally during these episodes she vomited small amounts of green, bitter fluid and had shaking chills. Four months before entry vague epigastric distress developed and often interfered with her sleep. The discomfort bore only a questionable relation to meals and was not relieved by soda. At no time did the vomitus contain blood or coffee grounds, and she never had diarrhea, constipation, jaundice, melena or weight loss. Nine days before admission a physician felt an egg-sized lump in the abdomen and advised hospitalization.

The family history was noncontributory. The menopause had occurred seven years before entry,

and the uterus was removed because of fibroids three years later.

Physical examination revealed a sallow, middle-aged woman in no distress. The examination of the heart was negative. A few crackling rales that did not disappear on coughing were audible at the base of the right lung. In the upper midepigastrium just below the xiphoid there was an egg-sized, firm, rounded, slightly tender mass that was quite movable, descended only slightly with respirations and seemed to pulsate.

The temperature was 98.9°F., the pulse 81, and the respirations 19.

The urine was negative. The blood Hinton was negative. A barium meal revealed a normal esophagus. There was a pressure defect on the lesser curvature of the stomach in the region of the angle; this was due to extrinsic pressure, and there was no evidence of intrinsic disease. The duodenal loop was not remarkable. At the end of six hours the barium lay on the proximal colon.

On the fourth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. ERNEST DALAND: This patient's symptoms really date back four months although there were indefinite symptoms before that. She had had no vomiting of blood or coffee-grounds material, suggesting that her difficulties had no intrinsic relation with the stomach. There was no diarrhea, constipation or jaundice, which is important. She had had a hysterectomy four years before entry. It is presumable that the operator passed his hand around the epigastrium at the time of operation and that this mass was not there at that time. An egg-sized, firm, round, slightly tender mass was felt at this admission. Those of you who have operated on an extensive cancer of the stomach that has not been felt beforehand must have been impressed with the size of a tumor that can be hidden in the epigastrium without being palpable. Here we have an egg-sized mass that the local physician felt, and also the man on the ward.

The first thing one would have to think of is an epigastric hernia. There is no note whether there was any impulse on cough, but many times in an epigastric hernia there is no impulse. However, as we go on and find that the x-ray films showed a pressure defect on the stomach I think we can rule out anything in the abdominal wall. There was something within the abdomen.

I should like to see the x-ray films. The number of structures that we have to consider in this region are distinctly limited. The left lobe of the liver may sometimes be palpated but would not be picked up as an egg-sized mass. The pancreas is

located here, as well as the stomach wall, the lymph nodes along the lesser curvature and the aorta. These are the organs that we have to consider.

DR. MILFORD D. SCHULZ: This I believe is the defect caused by the extrinsic mass that was described. You can see that the rugal folds pass uninterrupted over the area. The same is true in this spot film, which confirms the opinion of the fluoroscopist that this was an extrinsic mass. I think we might note that there is no evidence of erosion of the vertebrae so far as can be seen on these films.

DR. DALAND: Might it be something in the stomach wall and still have the rugae normal without ulceration?

DR. SCHULZ: Yes; but you would expect to see some displacement of the folds as they pass over the mass in the stomach wall. If it is intramural, there is usually some point of ulceration.

DR. TRACY B. MALLORY: However, myomas can be pedunculated and hang externally and not necessarily show any thickening of the stomach wall.

DR. SCHULZ: Yes; but then it often shows some evidence of tug on the stomach.

DR. DALAND: First is the question of aneurysm. The mass was said to be pulsating. There is no note whether there was any bruit on stethoscopic examination, or whether there was any expansile pulsation. There are no lateral films. A lateral film would probably have been taken if they had a strong suspicion of aneurysm, since it might have demonstrated erosions of the vertebrae that could not have been seen in the anteroposterior view. I think we can discount the possibility of aneurysm. In this plain film there is a shadow. Is it a mass?

DR. SCHULZ: It is rather indefinite.

DR. DALAND: I was given permission to look at these films before the conference and that was the only suspicious thing that I saw.

DR. SCHULZ: Of course, it could be a mass.

DR. DALAND: The pancreas is the next thing to be considered—a cyst of the pancreas or a tumor of the pancreas. Ordinarily, pancreatic cysts are in the loop of the duodenum—that is, if they arise in the head of the pancreas. However, the pancreas does extend across the midline at about this point and it would be possible for a cyst of the pancreas to present here; a lateral view would help a good deal in deciding whether the stomach was pushed forward. I thought tumor of the stom-

ach wall was a definite possibility; a benign leiomyoma of the stomach wall which had been there for some time might produce this picture. A malignant leiomyosarcoma would probably have ulcerated by this time and would give a defect on the inside of the stomach. The commonest tumor of the stomach next to carcinoma is leiomyoma, and I think that that is a decided possibility.

The other possibility is lymphoma. Such a tumor may occur in any place where there are lymph nodes, and this is a suitable location. There is no evidence of lymphoma anywhere else, and since the difficulty had apparently been going on for four months, I think that if it had been lymphoma there would have been other evidence of the disease.

I believe that this was a cyst of the body of the pancreas.

DR. FRED A. SIMMONS: I assisted at the operation on this patient. The house officer was given his choice of diagnoses after having had the privilege of palpating the abdomen under anesthesia; he chose pancreatic cyst. I was given a choice and chose leiomyoma of the stomach. The surgeon with his mature judgment said hydrops of the gall bladder. The mass was definitely to the left of the midline and larger than an egg, being 10 cm. long and 5 cm. broad. It was hard, movable and not adherent.

CLINICAL DIAGNOSIS

Hydrops of the gall bladder?

DR. DALAND'S DIAGNOSIS

Cyst of body of pancreas.

ANATOMICAL DIAGNOSIS

Hydrops of gall bladder.

PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was explored and an enormous gall bladder was found, which crossed anterior to and above the stomach, producing a pressure defect on the lesser curvature. When finally explored, it turned out to be even bigger than it seemed under anesthesia. It was 15 cm. in length and nearly 10 cm. in diameter, and it contained clear mucinous fluid and a considerable number of stones. I also called it a pancreatic cyst when I read the record, Dr. Daland. A lateral x-ray examination would probably have told the story.

SUBSCRIPTION TERMS: \$6.00 per year in advance postage paid for the United States (medical students \$3.50 per year); Canada, \$7.00 per year; Boston funds \$8.52 per year for all foreign countries (belonging to the Postal Union).

MATERIAL for early publication should be received not later than 10 a.m. on Friday.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

CONTRIBUTORS should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston, Massachusetts.

THE LABORATORY IN WARTIME

Now that medical personnel has been heavily depleted for the needs of the armed services, it becomes increasingly important that the practitioners still caring for the civilian population be able to carry on the work they do with the highest degree of efficiency.

An important factor in diagnosis and in the control of treatment is the information made available by the laboratory. The aid that a positive serologic reaction for syphilis may give in unraveling a diagnostic puzzle is as striking as the information that roentgenologic examination gives to the surgeon in a case of fracture or that hematologic studies afford to the internist studying a case of pernicious anemia or leukemia. Hardly the surgeon who trusts to his gross examination

of a removed lesion to determine whether malignancy is present.

One of the striking developments in medicine of the past two decades has been the phenomenal expansion of the use of the laboratory. Laboratory procedures have opened up new investigative techniques and have done much to simplify the understanding of many pathologic processes. So much can be done by the laboratory that it has sometimes received an unfair share of the diagnostic burden. Fifteen years ago the determinations of blood sugar levels, of sedimentation rates and of the amounts of serum protein were more or less rarities; but today, fortunately, they are matters of everyday performance and a requisition slip sent to the laboratory elicits prompt information concerning the desired test.

These laboratory procedures have different degrees of usefulness, and the complexity and reliability of the tests also vary to an appreciable degree. Such tests as the number of white cells, the amount of hemoglobin and the level of non-protein nitrogen in the blood may be carried out with great accuracy and dispatch. On the other hand, methods such as the hippuric acid test for liver function and the test for serum amylase may be neither accurate or informative.

Although it is easy in most hospitals to requisition any amount of laboratory work, all too often these studies are demanded without regard to the clinical condition of the patient and without any clear idea of what positive information may be obtained and what are the limitations of the tests. Much laboratory work that is useful under a certain set of circumstances is valueless or of academic interest under others, and it is worth while for the physician to check over his written orders from time to time to make sure that he really gets significant and useful information from the laboratory. Thus, several years ago pneumococcal typing was of great importance as an emergency procedure. Now, with the widespread use of the sulfonamides typing is unnecessary except in those cases in which serum therapy is also used.

Laboratories have suffered by the loss of pathologists and by the loss of technicians, and a curtailment of the scope of their work is inevitable. If their important help is to be utilized to best advantage, it is essential that there be discrimination by the practitioner in the laboratory tests that he requisitions. Thus, the performance of a complete blood count is undoubtedly of some interest in every patient seen. Unless there is some clinical indication to the contrary, however, a hemoglobin determination is all that is actually necessary, and if it proves abnormal, this serves as a starting point for further investigation. Similarly, a serologic test for syphilis is desirable for every patient, but there is rarely need for this request to be accompanied by one for gonococcal complement fixation and typhoid, paratyphoid and undulant fever agglutination.

Another waste in laboratories is the performance of scattered tests at frequent intervals. Many tests are not of an emergency nature. It is most conserving of laboratory personnel and material if several such tests can be done at the same time, even though it entails two or three days' delay. In this group fall such tests as the determination of blood calcium and phosphorus, of blood cholesterol, and of serum phosphatase.

It also behooves each pathologist to check over the work done in his laboratory, to make sure that there are no ways overlooked in which the available material and personnel can be used to better advantage. Even the tissue pathologist might well consider whether the lengthy microscopic descriptions that take his time to dictate, the secretary's time to typewrite and the surgeon's time to read are really worth the effort and give enough additional information to justify their retention in place of the microscopic diagnosis alone.

All too often in these days it is difficult to get adequate laboratory work done for the patient outside the hospital, and it is almost impossible for the physician to have a technician in his own office. Fortunately, several private laboratories and some hospital laboratories are available for the carrying out of essential labora-

tory tests for such patients. It might be well worth while for all hospital administrators to consider making available the laboratory facilities of their hospitals, so far as it is possible without impairing efficiency, to those practitioners who find themselves in need of data the laboratory can supply.

SAFE DELIVERANCE

A NEW book by a Boston physician, Dr. Frederick C. Irving,* deserves special attention.

The text is divided into three sections. The first is an autobiography of the author, written in an engaging style. There is much of interest in the account of his early life, particularly regarding his grandfather, a physician who practiced in northern New York, served through the worst battles of the Civil War and passed on his enthusiasm for medicine to his grandchild. Dr. Irving has paid a fine tribute to a man of character and *makes one realize that many of the best things in medicine are not entirely due to the great advances in recent years—character in a physician is still a primary and necessary asset.* Then come reminiscences of life in Harvard College at the turn of the century and of teaching at Harvard Medical School. The chapters on experiences at the Boston Lying-in Hospital on McLean Street are of great interest, and no one except the inimitable "Fritz" Irving could tell the story as he has done it. There are descriptions, too, of his period as a house pupil at the Massachusetts General Hospital, of which those dealing with the life in the hospital itself and with sidelights on Maurice Richardson and other surgeons are of particular interest. After a brief interval of war service, Dr. Irving returned to this country in 1919. He first assisted Dr. Franklin S. Newell and later succeeded him as chief-of-staff at the Boston Lying-in Hospital and professor of obstetrics at Harvard Medical School.

The second part of the book concerns the history of the Boston Lying-in Hospital, beginning

*Irving, F. C. *Safe Deliverance*. 308 pp. Boston: Houghton Mifflin Company, 1942.

in the earliest days of its existence, more than a hundred years ago, under the guidance of Walter Channing. To him are credited two outstanding contributions to medicine—his description of the anemia that occasionally complicates pregnancy and, of more importance, his introduction of anesthesia in childbirth. Here the story is especially well done, and each chapter is full of enlightening and often amusing anecdotes. Channing was followed, after an interval, by David H. Storer and later by his son, Horatio R. Storer. Both were outstanding obstetricians and contributed greatly to the knowledge of the art. The watchword of the first Storer, "Patience and expectancy up to the proper time for interference: prompt and fearless action when that time comes," should, as Dr. Irving notes, adorn the walls of every delivery room and lying-in chamber. To the second Storer should go the credit for the first operation to remove the uterus at the time of cesarean section, performed in 1868, eight years before the classic monograph by Porro, of Milan. Storer, like Long in the ether controversy, failed to realize the significance of what he had done, and his contribution was lost in the passing of time. Later came William L. Richardson and a host of others who kept the name of the Boston Lying-in Hospital at the front in the advancement of obstetrics in America.

Finally there are chapters on general topics: puerperal fever and the importance of Oliver Wendell Holmes's contribution to the subject, first published one hundred years ago this April; the matron of the hospital, Mrs. Higgins, who served from 1873 to 1914; midwifery in general; abortion, therapeutic and otherwise; puerperal convulsions; cesarean section; legitimacy; and the modern practice in obstetrics.

Throughout the book are notes on the teaching of obstetrics in Harvard Medical School and, indeed, important contributions to general knowledge concerning the teaching of the whole subject of medicine. There are many quotable passages: for example, "The most effective teacher is not the colorless intellectual virtuoso who today

deals out as a fact what tomorrow may prove to be only a fancy, or who pursues some petty experimental project; but he is the real doctor who transmits to his pupils the heritage of truth, courage, and kindness that will make his spiritual heirs worthy members of the medical profession."

The book is carefully written and surprisingly full of factual historical material, while enough lightness is given on each page so that a layman may read with both understanding and pleasure. The omission of an index cannot be overlooked, and a chronological tale of events and persons connected with the Boston Lying-in Hospital as an appendix would have greatly aided the average reader.

This is one of the best autobiographies of a doctor published in recent years. Every physician in New England will be delighted with the story unfolded by Dr. Irving. There is plenty of local color, and occasionally a pungent statement, but nothing at any time that will raise a blush in the most fastidious cheek. To the physician outside of the sphere of events ordinarily encompassed by the Boston Lying-in Hospital, this book will be welcome, for in it he will find a rich store of wise comments by a man of broad vision, particularly interested in life, and at the same time a practical, earnest, up-to-date leader of medicine.

MEDICAL EPONYM

STEENSEN'S DUCT

Niels Steensen (1638-1686) was born a Danish Protestant, studied medicine, gave up scientific investigation at the age of thirty-five, and died a Catholic priest at the age of forty-eight. He wrote under the Latinized form of his name Nicolaus Stenonis, and is often called Steno under the misconception that this is the nominative form of the supposed genitive Stenonis. The following account of his discovery of the parotid duct is taken from a letter to Thomas Bartholin, dated Leyden, April 22, 1661, and appears in the first volume of *Nicolai Stenonis Opera Philosophica* (Copenhagen, 1910: pages 3-7). The discovery was made in Amsterdam on April 7, 1660, while Steensen was a pupil of Gerard Blaes, director of the Town Hospital. A portion of the translation follows:

It is now a year since I, having become the recipient of Blasius's hospitality, and marking in that acquaintanceship—to which he put an end the third week after my arrival—a convenient opportunity for studying anatomical subjects, begged the famous man to allow me to dissect with my own hand whatsoever things I should be able to gather together for myself. Having obtained this permission, I was so favored by fortune that in the very first thing which I began to dissect alone—a sheep's head that I had bought at Museolus on April 7—I discovered a duct which, so far as I know, had never yet been described by anyone. I had removed the usual covering layers and was contemplating the dissection of the brain, when by chance I decided to examine first the vessels of the mouth. And so, to this end exploring the courses of the veins and arteries by inserting a probe, I noticed that the point, when driven but a short way in between the narrow layers, wandered around quite freely in a spacious cavity, and soon, when I pushed the metal probe farther, I heard the sound of it against the teeth themselves.

Struck by the novelty of this, I summoned my host to hear what he thought about it: he first began to accuse me of using force, then to resort to the explanation that it was one of Nature's many tricks, and finally turned to consult Wharton. But he could find nothing there either: and since the carelessness with which I had treated the vessels did not allow a more extensive examination, I resolved to repeat this investigation with greater care; and this I did a few days afterward, using a dog's head, although the results were not so clear. Since, therefore, the use of the vessels was proved by the similarity existing between large and small, I sent word in that same month to my close friend, the excellent Master Jacob Henry Paul, telling him that I had found a certain salivary vessel, and appending thereto some sort of description of it. Since, however, I knew that something similar to this had already been previously discovered, and was unable to learn whether or not it was the *same* thing that had been noted by others, I kept silence, until an opportunity presented itself to consult the great Sylvius on the matter. He, on learning my story, resolved to conduct an investigation, using a human body, and finding my story to be true, demonstrated it on numerous occasions in the presence of observers.

You have here, illustrious Sir, the history of the discovery. . . .

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON MATERNAL WELFARE

ANALYSIS OF CAUSES OF MATERNAL DEATH IN MASSACHUSETTS DURING 1941

MISCELLANEOUS

During 1941 there were two fatal cases of pernicious vomiting. One of these was that of a woman who had two living children. In this, her third pregnancy, she reported first to her physician six weeks after the last period. At that time she had severe vomiting. She was treated at home for ten days with some improvement but was finally sent

to the hospital because of a return of the vomiting. The blood pressure on admission was 90 systolic, 60 diastolic, and the pulse 130. The urine contained large traces of albumin. The patient was jaundiced. For ten days she was treated conservatively, but continued to go downhill; at the end of that time the nonprotein nitrogen was 117 mg., and the urea nitrogen 51 mg. per 100 cc. A consultation was held, and an abortion was advised; but so far as can be made out from the record, the patient died without operative interference. It is difficult to understand how a patient could, under such close medical care as this, have been allowed to die without operative intervention unless certain scruples contraindicated this procedure. Medically speaking, this was an entirely unnecessary death.

The second patient was a twenty-four-year-old primipara, who at the beginning of the pregnancy apparently had a pyelitis. This was treated in a hospital and cleared up. Excessive vomiting, described as pernicious, developed, and abortion was advised. Abortion was accomplished by packing the cervix. The entire fetus was expelled spontaneously. The temperature rose to 104°F. that evening, and the patient died within forty-eight hours of delivery. As fever developed the night following the operation, it was apparent that the operation was the cause of the infection. No autopsy was obtained, but one can attribute this unnecessary death solely to infection following an operation for pernicious vomiting.

There were two cases in which shock and, probably, hemorrhage were responsible for death. The first was that of a patient who had had one early miscarriage. The second pregnancy was normal in its prenatal course. The patient had a rather long labor. Delivery was accomplished, after forceps had failed, by version and craniotomy. The patient lived about an hour after delivery. There was no transfusion. There is little to be said about this case except that it was handled poorly and that the patient should undoubtedly have had a cesarean section. When one has to resort to version, because forceps-delivery is impossible, it is evident that a mistake has been made. And although there was considerable bleeding in this case, the prolonged operative procedure undoubtedly caused the shock that resulted in death.

The second case was that of a multipara who had three living children. She entered the hospital because of a mild hydramnios and albuminuria. Labor was induced with castor oil and rupture of the membranes, but did not proceed satisfactorily. It is evident that the cervix had not softened and was not amenable to induction by this method. After twenty-eight hours of labor a Waters's extra-

peritoneal cesarean section was done because it was believed that a Brindley ring had formed. The baby weighed 10¼ pounds. The patient was transfused eight times but died four hours later of hemorrhage and shock.

Two patients died of cerebral hemorrhage. On one of these the history is incomplete. At seven months it is said the patient had a cerebral hemorrhage and succumbed undelivered. The second patient had been treated for hypertension for two years. When eight months pregnant a cerebral hemorrhage resulted in paralysis of the right side. She was admitted to the hospital and died three weeks later, undelivered. A post mortem cesarean was immediately performed, and a 5 pound living child was secured. The only sure way to have eliminated this fatality was to have prevented pregnancy.

There were two cases in which, after investigation, the direct cause of death could not be determined. The first case was that of a woman who had had six previous normal pregnancies, the children were living and well. When seven months pregnant, while at a children's clinic, she fainted and was unconscious for an hour. She was immediately sent to the hospital in extreme shock. There was no bleeding and no abdominal spasm, the pulse was 150, no fetal heart could be heard. She started labor ten hours later and delivered a still born baby. Since there was no hemorrhage or excessive clots associated with the birth of the baby, premature separation of the placenta can be ruled out. During convalescence she vomited frequently but gradually improved. Suddenly an attack similar to the initial attack, with unconsciousness and pain in the epigastrium, occurred, from which she did not recover. Unfortunately, no autopsy was performed. Because of the rapid pulse and because of the pain in the abdomen and vomiting, it seems likely that a viscus ruptured. The second case was that of a woman in her fourth pregnancy who had had three previous cesarean sections. This pregnancy was terminated by a cesarean section at term. Spinal anesthesia was given. A minute after pituitary extract had been given, the patient had difficulty in breathing and a tickling in the throat. She suddenly became pulseless, and no blood pressure could be obtained. The pulse returned, but an hour and a half later, laryngeal spasm developed and she again became pulseless. Death followed almost immediately. No autopsy was performed, but it is possible that a hypersensitive response to pituitary extract was the cause of this catastrophe.

There were two cases of suicide. In one of these, the patient at term, arrived at the hospital dead, she was at term but not in labor. The cause of

death was ascertained to be poisoning from drugs. The second case occurred in a primipara, who shot herself through the head, undoubtedly while mentally deranged.

MISCELLANY

RESUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR NOVEMBER, 1947

DISEASES	NOVEMBER 1947	NOVEMBER 1941	PER CENT AVERAGE
Acute poliomyelitis	2	10	5
Cerebral malaria	969	117	1035
Scarlet fever	6	14	16
Diphtheria	583	687	67
Infectious mononucleosis	30	46	48
Cerebral meningitis	67	59	33
Cerebral pneumonia	38	337	422
Neisseria meningitidis	103	457	635
Neisseria meningitidis (serotype 1)	13	14	6
Meningococcus (other forms)	6	7	1
Typhoid fever	639	997	300
Paratyphoid fever	7	5	5
Shigellosis	234	193	264
Amoebiasis	883	734	486
Trachoma	535	397	455
Unidentified	239	199	200
Leishmaniasis	20	23	21
Wuchereria bancrofti	0	2	6
Urticaria	0	5	4
W. bancrofti	900	710	626

* Includes cases for preceding five years.
† Includes men, its only other form reportable previous to 1941.

Actinomycosis was reported from Springfield, 1, total 1.

Anterior poliomyelitis was reported from Fitchburg, 1, Lynn 1 total 2.

Anthrax was reported from Lynn, 1, total, 1.

Diphtheria was reported from Boston, 2, Lowell, 3, Springfield 1 total 6.

Dysentery bacillary, was reported from Cambridge, 1, Camp Edwards 1 Fall River, 5 Waltham (Walter E. Fernald State School), 5, Wrentham (State School), 18, total 30.

Encephalitis, infectious, was reported from Everett, 1, total, 1.

Malaria was reported from Camp Edwards, 1, Middleboro 1 total 2.

Meningitis, meningococcal, was reported from Boston, 2 Cambridge 1 Camp Edwards, 1, Dracut, 1, Fort Branks, 2, Lowell 1 Milton 1 Norwood, 1, Randolph, 1, Stoneham 1 Wilmington, 1, total, 13.

Meningitis other forms was reported from Boston, 1, Cambridge, 3 Fitchburg 1, Worcester, 1, total 6.

Paratyphoid infections were reported from Boston, 2, Lowell 1 Newton 2, Salem 1, Worcester, 1, total, 7.

Septic sore throat was reported from Attleboro, 4 Beverly, 1 Boston, 3, Braintree, 1 Fall River, 1, Fitchburg 1 Quincy, 2, Worcester, 1, total, 14.

Trachoma was reported from Boston, 1, Norwood, 1, total 2.

Typhus fever was reported from Camp Edwards, 1, total 1.

Although the usual high seasonal levels characterize certain of the communicable diseases for November, there were two outstanding exceptions. Typhoid fever, for the first time since the disease was made reportable, is conspicuous by its absence no cases having been reported during November. Undulant fever, too, was not reported.

Preventive Medicine in Modern Practice. Edited under the auspices of the Committee on Public Health Relations of the New York Academy of Medicine. By James A. Miller, Sc.D., M.D., D.P.H.; George Baehr, M.D.; and E. H. L. Corwin, Ph.D. Third edition. 4°, cloth, 851 pp., with 22 illustrations and 37 tables. New York: Paul B. Hoeber, Incorporated, 1942. \$10.00.

This is not a textbook of preventive medicine, but "an attempt to combine in one volume the clinical and environmental aspects of health problems in a manner suited to the needs of both the general practitioner and the specialist." The defect most obvious in such a synthesis is well expressed by one of the fifty distinguished co-authors, Dr. Edgar van Nuys Allen, who contributes the chapter on degenerative diseases, "In the light of present knowledge there is too little fact and too much fancy, too little evidence and too much opinion, and too little knowledge and too many questions."

The book is divided into four sections: sociobiological aspects, clinical aspects, environmental aspects and organizational aspects. It is inevitable that there should be considerable variation in the quality of the many chapters. Of outstanding interest and value are the following: "The Prevalence of Disease," by Haven Emerson; "Tuberculosis," by James A. Miller; "Heart Disease," by Paul D. White and "Provision for the Care of the Sick," by Ray Lyman Wilbur.

It can be heartily recommended to the practitioner of medicine as a means of orienting himself in a field that is certain to be invaded in progressively larger numbers by an army of zealots who will seek to dominate it by legislative and political measures. It is not recommended as a satisfactory text for medical students.

History of the School of Nursing of the Presbyterian Hospital, New York: 1892-1942. By Eleanor Lee, A.B., R.N. 8°, cloth, 286 pp., with 58 illustrations. New York: G. P. Putnam's Sons, 1942. \$3.50.

This is an excellent history of the development of the nursing school in one of the leading hospitals in the country. Of particular value are the illustrations. Miss Lee seems to have found many of them, and not a few may be considered unique. There is, for instance, an excellent picture of the operating theater in 1903, and another showing the parade of the American nurses in Paris on July 4, 1918. This is a book, therefore, that will have an appeal far beyond the average history of a hospital nursing corps. It is a historical document of considerable importance and should find its way into all medical libraries, as well as into the hands of physicians interested in medical history.

Standard Radiographic Positions. By Nancy Davies, M.S.R., and Ursel Isenburg, M.S.R. 8°, cloth, 136 pp., with 103 illustrations. Baltimore: The Williams and Wilkins Company, 1942. \$2.00.

This small book deals with the positioning of patients for roentgen examination and was written by two English technicians. It is stated in the preface that there was real need for such a book in England. Whether or not that be true, there seems to be little need for publishing it in this country since it adds nothing to the standard American texts on x-ray technic.

There is a simple statement concerning how the patient should be placed for each examination, and there is a sketch depicting the end result; but there are no photographs to show clearly the patient in the desired position, and no attempt has been made to reproduce the resulting radiograph.

Health Education of the Public: A practical manual of technic. By W. W. Bauer, M.D., and Thomas G. Hull, Ph.D. Second edition, revised. 8°, cloth, 315 pp., with 52 illustrations. Philadelphia: W. B. Saunders Company, 1942. \$2.75.

This volume has been compiled in an effort to help physicians who are preparing medical material for the use of the public. It covers chapters on the radio, the exhibit, the meeting, the pamphlet, the newspaper, the magazine article, the motion picture and the use of stereopticon slides. Detailed information on all phases of health information is given, such as, samples of the different sizes of type, criticism of posters, the making of stereopticon slides, the cost of printing pamphlets and the arranging for public meetings.

Of particular interest are the pages devoted to technical words used in articles written for the public. These words are divided into four groups—those which should not be used and for which a synonym is available, those which must be used because of a lack of a proper synonym, those which are technical but also familiar and can be used, and those which under no circumstances should be used.

In the foreword of the book Morris Fishbein states, "The physician or the worker in the field of public health will find here opportunity to accumulate in a short time knowledge which otherwise might be gained only with great difficulty and at considerable expense by the old system of trial and error."

This book can be recommended to all physicians helping to educate the public on medical subjects and to nonmedical workers in health education.

Urology in War: Wounds and other emergencies of the genito-urinary organs, surgical and medical. By Lieutenant Commander Charles Y. Bidgood (MC), U.S.N.R. 8°, cloth, 78 pp., with 27 illustrations and 3 tables. Baltimore: The Williams and Wilkins Company, 1942. \$2.00.

This book describes, in condensed form, the essential features of traumatic lesions and inflammatory conditions of the genitourinary tract, and acute nontraumatic and noninflammatory lesions of the penis and scrotal contents. Brief review of the regional anatomy is included, and the treatment of each condition is outlined. There is a chapter on acute retention, one by Lloyd Lewis on bladder dysfunction after cerebrospinal injury, and one by Ralph Tovell on anesthesia in urology.

Although the material is condensed, it is sufficiently explicit to enable any intelligent medical officer to apply the principles in actual practice. The illustrations by Didusch are, of course, excellent and help greatly in clarifying the operative technic.

A few criticisms are worth noting. For example, the use of sulfathiazole in the peritoneal cavity (page 13) is not generally approved, sulfanilamide being preferred. In a perineal operation for stricture, the reviewer believes that simple longitudinal incision of the floor of the urethra through the stricture is more practical than an attempt to dissect the scar tissue off the outer wall of the urethra (page 40), since a stricture involves the mucosa, and the close approximation of the vascular tissue of the corpus spongiosum is likely to make such an attempt result in profuse hemorrhage. Aside from these minor criticisms, the book is consistent with the generally accepted views of urologists; it should prove helpful in emergencies involving the genitourinary tract.

NUMBER 6

GOVERNMENT'S OBLIGATION IN INDUSTRIAL HEALTH*

WARREN F. DRAPER, U.S.P.H.S.†

WASHINGTON, D. C.

WE MEET today at a time of revolutionary changes. In the field of industrial health, as elsewhere, the changing conditions are giving rise to new problems, which we must be prepared to face. First there are the changes in the composition of the labor forces. Older men, women, the physically handicapped and, in some industries, veritable youngsters are all going to work. The chairman of the War Manpower Commission has mentioned a working army of upward of 60,000,000. As we approach this number, we must leave out men of Class 1-A or 1-B selective qualifications. There is a distinct probability that we must also leave out the eighteen- and nineteen-year-old boys. These workers, steadily increasing and without the physical adaptation and experienced work-habits of the men who have been called into service, are laboring harder and for longer hours than heretofore. Eight federal agencies—the Maritime Commission, the War Manpower Commission, the War Production Board, the Department of Commerce, the Department of Labor, the War Department, the Navy Department and the Public Health Service—have jointly subscribed to a policy of urging a forty-eight-hour week limit in war plants. This policy is in line with a statement issued by the Public Health Service nine months ago pointing out that industries operating on a twenty-four-hour-a-day basis must take special precautionary measures to minimize the effects of night work and the rotating shift.

Another important change has been brought about by the growth of boom-town conditions in many areas. The three basic essentials of public health—safe water, safe food supplies and proper sewage disposal—are jeopardized, especially in the more recent industrial and military mobilization areas. Add to this the problems of crowded clinics and hospitals, crowded housing and crowded transportation, and we have a situation that calls for

the best services that our federal, state and local health authorities in combination have to give.

Perhaps the fastest and biggest changes have taken place in our factories. New processes, new machinery, new materials are now in use. Often they have been introduced too rapidly to receive the benefit of investigation from the standpoint of their effect on health. Of course, many of the health hazards are already too well known to call for further research. Welding, dermatosis-producing materials, siliceous dusts, benzol—these four potential occupational hazards come quickly to mind as examples of processes and substances whose dangers we have known for some time. But this easily available scientific knowledge has not been applied in our factories as completely as possible. There is only one way to bridge the gap between knowledge and application. That is by employing trained personnel to do the job. An insufficient supply of trained personnel is one of the great difficulties we have to face in industrial health conservation. Today there are approximately five hundred professionals and technicians in this country trained in the particular complexities of industrial hygiene. Five or six years ago there was hardly one fifth of the present number. Fortunately, the Public Health Service recognized the need at that time. We believed that it was our responsibility to help meet it and to stimulate similar preparation by industry, medicine and professional and technical schools. Each year since 1936 our Division of Industrial Hygiene has run orientation courses for in-service and field training. Without this preliminary start it is doubtful whether we could have handled the sharp upswing of demands for industrial-hygiene services—demands that were motivated largely by the conditions I have just described.

The first big job of the Public Health Service is that of directly assisting the War Department. The Division of Industrial Hygiene has completed surveys of eighty of the one hundred and fifty gov-

It is not recommended as a satisfactory text for medical students.

History of the School of Nursing of the Presbyterian Hospital, New York: 1892-1942. By Eleanor Lee, A.B., R.N. 8°, cloth, 286 pp., with 58 illustrations. New York: G. P. Putnam's Sons, 1942. \$3.50.

This is an excellent history of the development of the nursing school in one of the leading hospitals in the country. Of particular value are the illustrations. Miss Lee seems to have found many of them, and not a few may be considered unique. There is, for instance, an excellent picture of the operating theater in 1903, and another showing the parade of the American nurses in Paris on July 4, 1918. This is a book, therefore, that will have an appeal far beyond the average history of a hospital nursing corps. It is a historical document of considerable importance and should find its way into all medical libraries, as well as into the hands of physicians interested in medical history.

Standard Radiographic Positions. By Nancy Davies, M.S.R., and Ursel Isenburg, M.S.R. 8°, cloth, 136 pp., with 103 illustrations. Baltimore: The Williams and Wilkins Company, 1942. \$2.00.

This small book deals with the positioning of patients for roentgen examination and was written by two English technicians. It is stated in the preface that there was real need for such a book in England. Whether or not that be true, there seems to be little need for publishing it in this country since it adds nothing to the standard American texts on x-ray technic.

There is a simple statement concerning how the patient should be placed for each examination, and there is a sketch depicting the end result; but there are no photographs to show clearly the patient in the desired position, and no attempt has been made to reproduce the resulting radiograph.

Health Education of the Public: A practical manual of technic. By W. W. Bauer, M.D., and Thomas G. Hull, Ph.D. Second edition, revised. 8°, cloth, 315 pp., with 52 illustrations. Philadelphia: W. B. Saunders Company, 1942. \$2.75.

This volume has been compiled in an effort to help physicians who are preparing medical material for the use of the public. It covers chapters on the radio, the exhibit, the meeting, the pamphlet, the newspaper, the magazine article, the motion picture and the use of stereopticon slides. Detailed information on all phases of health information is given, such as, samples of the different sizes of type, criticism of posters, the making of stereopticon slides, the cost of printing pamphlets and the arranging for public meetings.

Of particular interest are the pages devoted to technical words used in articles written for the public. These words are divided into four groups—those which should not be used and for which a synonym is available, those which must be used because of a lack of a proper synonym, those which are technical but also familiar and can be used, and those which under no circumstances should be used.

In the foreword of the book Morris Fishbein states, "The physician or the worker in the field of public health will find here opportunity to accumulate in a short time knowledge which otherwise might be gained only with great difficulty and at considerable expense by the old system of trial and error."

This book can be recommended to all physicians helping to educate the public on medical subjects and to nonmedical workers in health education.

Urology in War: Wounds and other emergencies of the genito-urinary organs, surgical and medical. By Lieutenant Commander Charles Y. Bidgood (MC), U.S.N.R. 8°, cloth, 78 pp., with 27 illustrations and 3 tables. Baltimore: The Williams and Wilkins Company, 1942. \$2.00.

This book describes, in condensed form, the essential features of traumatic lesions and inflammatory conditions of the genitourinary tract, and acute nontraumatic and noninflammatory lesions of the penis and scrotal contents. Brief review of the regional anatomy is included, and the treatment of each condition is outlined. There is a chapter on acute retention, one by Lloyd Lewis on bladder dysfunction after cerebrospinal injury, and one by Ralph Tovell on anesthesia in urology.

Although the material is condensed, it is sufficiently explicit to enable any intelligent medical officer to apply the principles in actual practice. The illustrations by Didusch are, of course, excellent and help greatly in clarifying the operative technic.

A few criticisms are worth noting. For example, the use of sulfathiazole in the peritoneal cavity (page 13) is not generally approved, sulfanilamide being preferred. In a perineal operation for stricture, the reviewer believes that simple longitudinal incision of the floor of the urethra through the stricture is more practical than an attempt to dissect the scar tissue off the outer wall of the urethra (page 40), since a stricture involves the mucosa, and the close approximation of the vascular tissue of the corpus spongiosum is likely to make such an attempt result in profuse hemorrhage. Aside from these minor criticisms, the book is consistent with the generally accepted views of urologists; it should prove helpful in emergencies involving the genitourinary tract.

(Notices on page x)

tactics, then, must be to attack the problems of disease from two sides in a combined assault—in the community as well as in the factory.

The venereal-disease clinic, the nursing service, the dental service, the public-health education service, the sanitation section, the maternal and child-health service must reach the industrial worker and his family to a far greater extent than mere routine functions permit. The industrial-hygiene unit has a close, informed relation with management and employees, and therefore is the logical co-operative channel through which these services can reach the worker. The local health department, correspondingly, is the channel through which industrial hygiene can be brought to bear directly on the health problems of workers in small plants. The health officer has at his command the state industrial hygienists, who are trained and equipped to co-operate with him, just as he, by virtue of his position, has the most complete acquaintance with local needs and resources. In this sense, therefore, every division of a state or local health department should play a part in building the foundation for promoting the health of workers. If we agree on the changing nature and extent of our common problems, I think we shall agree that we must prepare for the possibility of changing our methods of dealing with them. As the ratio of physicians to population becomes dangerously low in many areas, we must consider the possibility of industrial doctors' leaving their dispensaries for certain periods of community prac-

tice. If a skilled man is off the job in order to care for his sick wife, it is common sense (as well as enlightened humanitarianism) to treat the woman so that the man can return to war work, where every pair of hands is needed. It would seem that the day is coming when, in many areas, the community physician's practice and the plant physician's patients will have to be handled by *one* and the same man. That man should have—and must have—the co-operation of every governmental agency. He should have—and must have—the understanding and backing of his medical society. He must have the co-operation of the war-production-drive labor-management committees. He must have the same respect, encouragement and attention that top management already gives to operations departments. Last and not least, he must have the friendship and understanding of the workers whom he treats, for only they, in the final analysis, can apply to their daily lives the precepts that he teaches.

All of us, no matter in what field we work, have a single star to steer by. That is the belief that every man and every woman saved from illness or accident is a skill saved as well as a person saved. In the months ahead we shall need every skill, for it is only the total of our many skills on the home front and the battle front that will hasten the final victory. In a changing world, our determination to overcome any and all obstacles through constant effort and teamwork must remain changeless.

THE DIAGNOSIS OF SPRUE IN NONTROPICAL AREAS*

FRANZ J. INGELFINGER, M.D.†

BOSTON

SPRUE and spruelike states are not rare in northern latitudes, but the complicating features are often so prominent that the underlying disorder is not immediately recognized. Four patients seen within the last two years at the Massachusetts Memorial Hospitals illustrate not only the wide variety of symptoms encountered but also the ensuing diagnostic difficulties. In each of these cases initial failure to make the correct diagnosis postponed adequate therapy, which, in sprue, may not be completely curative but will often allow a severely debilitated person to resume a normal life. Hence reports of these patients are presented, not as complete case reports of sprue seen in nontropical areas, but in order to emphasize the secondary phenomena that may be encountered. Excellent descriptions of nontropical and tropical sprue, as well as complete case reports, can be found in the writings of Thaysen,¹ Snell,² Miller and Barker³ and Kantor.⁴

Spruelike states are characterized by steatorrhea, which apparently is not the result of pancreatic disease. Under this heading, tropical sprue, nontropical sprue (idiopathic steatorrhea) and celiac disease of children may be listed. Whether these conditions represent different aspects of the same disease is still a matter of dispute,^{1,2} but for the present purposes, the two adult forms will be considered under the single heading of sprue.

The outstanding feature of this disorder is an excess output of fecal fat, which has led to the conception that the basic abnormality of sprue is a malabsorption of lipids. It is more likely, however, that patients with this disease absorb all substances poorly, even water and gases; and absorption tests using glucose⁵ and glycine⁶ substantiate this conception with respect to sugars and amino acids. On the other hand, the small intestine of man is long enough to compensate for the delayed absorption rate of glucose and amino acids; hence these substances do not appear in the feces to excess. Fats, however, are much more slowly absorbed, even by the normal bowel, and a delayed lipid absorption then causes fatty substances to be spilled into the colon. This, in turn, leads to the fatty stools of sprue. Patients who have had extensive granulomatous disease, resections or short cir-

cuit of the small intestine may also have steatorrhea,⁷ but in these cases the curtailment of the absorbing surface rather than a generalized defect predisposes to the spruelike state. It is then clear that the symptoms of sprue may be predominantly related to the gastrointestinal tract and its disturbed functions; or these symptoms may be minimal, and the patient's major complaint will then be the result of a dietary deficiency conditioned by the poor absorptive capacity of the bowel. Naturally, a deficiency of fatty substances is most likely to occur.

STOOLS

Typically, the patient with sprue has frequent bowel movements consisting of soft, light-yellow, frothy and greasy fecal material. Actually none of the four patients consistently had stools fitting this description during the period that each was under observation, and two never passed stools of this character.

Patient H. S., an unmarried woman, thirty-one years old, of Syrian extraction, complained of gross hematuria of two days' duration. Because she gave the additional history of increasing fatigue, weight loss and hoarseness, the diagnosis of adrenal, laryngeal and renal tuberculosis was entertained. Only on direct questioning did the patient state that she had had an increasing frequency of bowel movements for two or three months. In the hospital, the movements were watery and dark brownish green. The high lipid content of these stools was grossly apparent only after they had been allowed to stand for several hours, when a thick layer of fatty material gradually accumulated on the surface.

Patient W. J., a man of forty-seven, who had been known to suffer from hypocalcemic tetany and from a macrocytic anemia moderately resistant to liver-extract therapy for four years, moved his bowels once daily and occasionally took mineral oil for constipation. Though he had no diarrhea, his stools were light and somewhat greasy in appearance. Sprue had not been considered in his case because of the formed character of the feces.

Patient W. C., a man of thirty-six, had the typical stools of sprue on admission, but after four months of treatment, bowel movements occurred only twice daily, one movement being formed, the other watery. Although the fat intake was limited to 25 gm. daily, the stools continued to be light yellow,

This study was aided by a grant from Brewer and Company, Incorporated, Worcester, Massachusetts.

†Assistant professor of medicine, Boston University School of Medicine; associate, Evans Memorial, and assistant visiting physician, Massachusetts Memorial Hospitals.

suggesting that this color is not necessarily produced by a high percentage of fecal fat

Fat balance studies on all three patients showed that they excreted 42, 25 and about 80 per cent* of their dietary fat, respectively (normal less than 10 per cent is excreted). But it is not necessary to do such laborious studies, in each of

the diarrhea, he suffered from abdominal distention and cramps. Eight months before admission to the hospital, he was awakened at night with particularly severe colic and distention, accompanied by some nausea and vomiting. An emergency operation for intestinal obstruction was done, but the laparotomy revealed no local lesions, merely a

*Patients H S and J M were expected to excrete 10 per cent of dietary fat.

these cases, a microscopic study of a fecal specimen stained with sudan III was enough to show the abnormal steatorrhea.

The stools of all these patients were cultured, but no pathogenic intestinal bacteria were identified. A heavy growth of *Parasaccharomyces A (Monilia albicans)*⁸ was, however, obtained from both the feces and the small bowel contents of patient W C. When the patient improved clinically, the *parasaccharomyces* disappeared from the stools, only to reappear when a mild relapse was precipitated by his failure to observe the prescribed dietary and therapeutic regimen. These observations are in accord with the now generally accepted belief that *parasaccharomyces* are secondary invaders, not etiologic agents in sprue.

DISTENTION AND CRAMPS

A well known symptom of sprue is abdominal distention, the result of abnormal accumulations of gas and liquids in the loops of the small and the large bowel. This distention has usually been ascribed to intestinal fermentation, but a better explanation can be found in the marked loss of intestinal tone, which prevents proper propulsion, elimination and absorption of gases. As in the distended bowel behind a partial obstruction, however, deep contraction waves may pass over the distended loops, producing typical abdominal colic. Usually the atonic symptoms greatly exceed those due to the hyperperistalsis, but not always. The combination of atony with occasional hyperperistalsis leads to the unusual intestinal pattern that roentgenologic studies have demonstrated in sprue.^{9, 11}

Patient W C had had intermittent bouts of progressively severe diarrhea for fifteen years. With

generally loose and flabby bowel stained diffusely with a brown pigment (hemofuscin). Nevertheless, an ileostomy was done. Since symptoms suggesting intestinal obstruction persisted, two more ileostomies were performed in a six month period, each ileostomy being placed higher than the previous one, and each being unsuccessful in alleviating the symptoms. Treatment of the sprue, after the diagnosis was finally made, relieved the symptoms promptly. In spite of all measures, however, this relief was not permanent. Occasional cramps and hyperperistalsis occurred but the negative findings at previous operations, as well as careful diagnostic studies with the Miller-Abbott tube, ruled out organic obstruction. An examination of this patient's stool before the first ileostomy would have pointed to the correct diagnosis and a combined diagnostic and therapeutic use of the Miller-Abbott tube^{12, 14} would have shown that the motor disorder was generalized, not local.

ANEMIA

The anemia that attends sprue may simulate that of pernicious anemia or may be hypochromic and microcytic.¹⁵ In these four patients, the variable hematologic characteristics of this disease are well illustrated in that two had microcytic and two macrocytic anemia (Table 1). The picture was complicated in patients H S and J M, however, since both suffered from purpura and had lost considerable blood at the time the diagnosis of sprue was first established.

When the mean corpuscular volume and the mean corpuscular hemoglobin are increased over their normal upper limits (92 cubic microns and 31 gamma gramma respectively), as was the case in patients W C and W J, the differential diagnosis between sprue and pernicious anemia may

*This patient had an ileostomy. Per cent excretion of fat was determined from the fat content of the fecal contents was impossible.

present some difficulties. As a matter of fact patient W. J. had been considered to have Addisonian anemia three years previously, because he had a red-cell count of 2,240,000, a hemoglobin of 55 per cent and gastric achlorhydria. This diagnosis, however, failed to explain the other findings—the disproportionately large abdomen, the attacks of hypocalcemic tetany and the rather disappointing response to therapy with parenteral liver extract. Usually one can expect that a potent preparation of liver will produce a dramatic response in pernicious anemia, particularly if the anemia is severe. In patients with sprue, liver extract also benefits the anemia, but the amount necessary for this result is often two or three times that needed in pernicious anemia, and a complete eradication is difficult to achieve.

TETANY

Each of the four patients had tetany at one or more periods during his or her illness. Usually the carpopedal spasms were recognized for what they were, but in one case (patient W. C.) a physician who failed to recognize that he was eliciting a Trousseau sign chided the patient when the inflation of the sphygmomanometer cuff around the arm produced a painful spasm of the hand and fingers. Even when Chvostek and Trousseau signs were not obtainable, the serum-calcium levels were below normal (Table 1).

Formerly this hypocalcemia was ascribed to the formation of insoluble calcium soaps in the intestine. Studies of the intestinal tract in man show, however, that the pH of the small bowel rarely rises above 7.5,^{16, 17} and in a medium with a pH of less than 8.0 many soaps do not form.¹⁸ Hence the suggestion of Albright and Stewart⁷ that faulty calcium absorption is a secondary result of poor absorption of the fatty vitamin D offers a more reasonable explanation of the hypocalcemia. Thus, for instance, massive therapy with vitamin D will raise the serum-calcium level in patients with steatorrhea.¹⁹ On the other hand, increasing the dietary fat in patients with sprue is followed by an increased output of fecal calcium.²⁰ These facts suggest that both mechanisms may play a part in producing hypocalcemia.

In spite of the low serum-calcium content, none of our patients showed definite osteoporosis of the long bones. The serum-phosphatase levels were normal.

These observations suggest that sprue should be suspected, as well as hypoparathyroidism and advanced renal disease, when evidences of hypocalcemia are found.

BLEEDING TENDENCY

Patient H. S., as already mentioned, entered the hospital with a chief complaint of hematuria, which was ascribed to a tuberculous renal lesion. Three days after the beginning of the hematuria, the patient commenced to bleed from the nose and mouth as well, and huge purpuric areas formed all over the body (Fig. 1). Only then was the cor-

FIGURE 1. *Distribution of Subcutaneous Hemorrhages in Patient H. S.*

rect diagnosis suspected. The prothrombin time had dropped to 1 per cent of normal. Patient J. M.* similarly developed massive purpuric areas within the course of two days, although he had had gastrointestinal symptoms for four years previously. Table 1 gives the prothrombin values in the series.

The cause of the prothrombin deficiency is in all probability the same as that of the hypocalcemia, namely, the failure to absorb a fat-soluble vitamin—in this instance vitamin K. Parenteral injection of the fatty vitamin or oral administration of a water-soluble preparation will immediately arrest the bleeding tendency in these cases. If the diagnosis is not correctly made, the patients may die of internal and external hemorrhages.

VITAMIN A DEFICIENCY

The symptoms of vitamin A deficiency are less dramatic than those of vitamin D or K deficiency, and therefore are often not apparent unless specifically investigated. Two of the patients complained of night blindness, but biophotometer measurements were not carried out. Gross xeroph-

*This case has been reported in detail by Kark, Souter and Howard.²¹

themia was not present. One patient had a dry, scaly skin, but in the presence of an associated deficiency of the vitamin B complex, the significance of this lesion was equivocal. On the other hand, the content of Vitamin A and its precursor, carotene, in the blood can be determined with considerable accuracy.²² Figure 2 shows that the

FIGURE 2. Vitamin A Absorption Test and Carotenoid Level in Sprue.

The values in sprue (solid lines and dots) are compared with those in normal persons (shaded area). The fasting figures are indicated at F. The scale on the right shows the fasting carotenoid levels in patients with sprue (three solid dots) and in normal persons (shaded area).

fasting levels of vitamin A in the plasma were strikingly decreased in the 3 patients in whom this determination was carried out, and that carotene was to all intents and purposes completely absent. Furthermore, after a large dose (250,000 international units) of vitamin A was given by mouth, little absorption occurred so far as could be told from the plasma levels. Low vitamin A levels in the plasma and flat absorption curves may, however, be found in other diseases (infections^{23, 24} and hepatic disorders²⁵), and do not necessarily indicate impaired absorption²⁶; but the very low carotene values are particularly significant in establishing the diagnosis of steatorrhea.

VITAMIN B-COMPLEX DEFICIENCY

Patients with tropical sprue often have striking evidence of deficiency of the vitamin B complex, especially of nicotinic acid and riboflavin deficiency. Patient W. C., who had had sprue for fifteen years, was the only one of the patients who exhibited these signs. Cheilosis, angular stomatitis and a dark-red and smooth tongue were promi-

nent. Also striking was the deep, fiery-red color of the mucosa of the proximal and distal portions of the ileum at the site of the ileostomy. Oral administration of 9 mg. of thiamin hydrochloride, 300 mg. of nicotinic acid, 5 mg. of riboflavin and six tablets of Brewer's yeast daily had no apparent effect on the oral and mucosal changes. When thiamine hydrochloride was given parenterally (10 mg. three times a day intramuscularly), an acute exacerbation of the stomatitis occurred. Within one week, the tongue became purple, multiple aphthous ulcers appeared, and the patient had to be given anesthetic mouthwashes for relief. Thereupon he was given parenterally a preparation of vitamin B complex said to contain 3 mg. of thiamine hydrochloride, 10 mg. of nicotinic acid amide, 0.5 mg. of riboflavin, 0.45 mg. of pyridoxine and 1.68 mg. of pantothenic acid per cubic centimeter. He received 2.5 cc. of this preparation daily as well as 2.5 cc. of a crude liver extract (1 unit per cubic centimeter). In three days the symptoms disappeared; one week later the tongue was pale and the fissures at the corner of the mouth had healed; and in one month the lingual papillae began to grow. During this time, the mucosa of the ileum became pinker and much less irritated in appearance.

These observations suggest that this patient was unable to absorb the vitamin B fractions which he was given by mouth, or that the oral doses contained insufficient quantities of the necessary materials. Since the oral doses were given over a period of two months, it is more than likely that the buccal and lingual lesions would have responded had this patient's absorption of riboflavin and nicotinic acid been adequate.

The other three patients had no gross evidence of impaired absorption of the vitamin B complex. This difference was probably quantitative, not qualitative; that is, patient W. C. had by far the greatest absorption defect in respect to all substances and had suffered from this defect for the longest period of time.

CLUBBED FINGERS

Manson-Bahr²⁷ mentions clubbing of the fingers as an occasional finding in nontropical sprue. Patient W. J. exhibited these digital changes. Since this sign has also been observed in patients with ulcerative colitis,²⁸ it appears that chronic malfunction of the intestine may be considered as one of the causes of clubbed fingers.

SUMMARY AND CONCLUSIONS

When sprue and spruelike states are encountered in nontropical areas, the classic features of tropical sprue may be absent or may be obscured

by the secondary nutritional disturbances of the disease. On the basis of observations made on four cases, it appears that the stools are not always numerous or greasy on gross inspection. The disorganized motor activity of the intestines may occasionally produce symptoms suggesting organic intestinal obstruction. In other patients, the gastrointestinal symptoms play a secondary role in the clinical picture, which may be featured by tetany, a generalized bleeding tendency or anemia. Vitamin A and particularly carotene are present in low concentrations in the plasma, and night blindness is at times noticed. Evidences of a deficiency of the vitamin B complex, such as stomatitis and glossitis, are not always found, especially in the nontropical variety of sprue. Occasionally digital clubbing is observed.

The diagnosis of sprue in these four cases was made respectively eight months, three years, four years and fifteen years after the onset of symptoms. This delay may be ascribed to the facts that this diagnosis is not considered in northern climates and that the typical picture of sprue may be obscured by such features as have been described. The diagnosis, once thought of, is not difficult to make, a simple sudan III stain of the feces usually being sufficient to determine the presence of steatorrhea. To establish the diagnosis completely, determinations of prothrombin, calcium and carotene in the plasma, roentgenologic studies of the small intestine and, possibly, pancreatic function tests may be necessary. In most cases, however, the clinical picture combining the characteristics of a chronic but noninflammatory intestinal disorder with anemia and evidences of deficiencies of vitamins A, D and K should be sufficient to bring the diagnosis of sprue to mind.

were normal. There were no thrills or murmurs, but the sounds were distant. An electrocardiogram showed a deep Q_1 and late inversion of T_3 suggesting an old posterior myocardial infarction.

The exercise tolerance test prior to testosterone propionate therapy ranged from 20 to 31 trips and the duration of the pain from 70 to 80 seconds. Improvement was reported by the patient after the fourth injection, but it was not until after the sixth injection that quantitative improvement was observed. This reached its maximum after the fourteenth injection, when he was able to make 51 trips before experiencing substernal pain, which lasted 53 seconds. The shortest duration of pain after therapy was 30 seconds (Fig 4). After the sixth injection the patient required only the occasional use of nitroglycerin.

DISCUSSION

The present study provides further evidence of the value of testosterone propionate in the treatment of angina pectoris. This agent not only reduces the frequency of the attacks but decreases their severity when they do occur. It is important, however, to stress that it does not give immediate relief from an anginal attack, as does nitroglycerin. Furthermore, the improvement after the use of this drug varies with the individual patient both in time of onset and in degree. Whereas some patients in this series showed improvement after the second or third injection of testosterone propionate, there were others in whom no improvement was noted until the eighth, ninth or even tenth injection. Again, some patients required as many as fifteen to twenty-five injections over a period of months before therapy could be discontinued. These considerations emphasize the importance of individualizing each case and of giving an adequately long course of treatment. It seems doubtful whether giving the drug more frequently would produce more favorable results, since the time element plays such a significant role in obtaining the desired effect. This is borne out by the results obtained in the group of patients reported here. An average of twenty-eight days elapsed before quantitative improvement was noted, and a period of forty-three days elapsed before this improvement became marked. Although it is recognized that spontaneous improvement may occur in some patients with angina pectoris over the course of weeks or months, it would be most unusual for this improvement to occur uniformly in a large series of patients in such a short space of time.

Since the beginning of the present study, not enough time has elapsed to determine the duration of the beneficial effects of testosterone propionate therapy. In the previous study¹ it was noted that this period varied with the individual patient. The shortest period of benefit was two months, whereas the longest period that a patient has been free of anginal attacks is eighteen months. It is significant that those patients who returned for further treatment because of a recurrence of pain reported that their attacks were less severe than originally, and furthermore it was found that fewer injec-

CASE 2. W. W., a 64-year-old physician, had a history of angina pectoris of 4 years' duration. The pain was brought on by climbing one flight of stairs or walking three or four city blocks, and was relieved by rest or nitroglycerin. He required 2 to 4 nitroglycerin tablets

before precipitating an attack and the pain lasted only 23 seconds (Fig. 2).

CASE 3. B. M., a 54-year-old boilermaker, had a history of angina pectoris of 9 months' duration that became

sidered, more recent articles by Bomford and Rhoads⁵⁶ present careful studies of this tissue. The term "refractory anemia" is in some respects unfortunate because it emphasizes refractoriness to therapy rather than the diverse etiologic and pathologic changes that are present. In my own experience, it is of distinct importance to determine the status of the marrow, the possibility of hepatic, splenic or thyroid disease, the presence or absence of a hemolytic process and the possibility of a disorder of fat metabolism, such as Gaucher's disease. Despite the reduction of red cells, white cells and platelets in the blood, the bone marrow at biopsy may be extremely cellular. Leukemia — myelogenous, lymphatic or monocytic — shows extreme leukocytic proliferation; lymphosarcoma and Hodgkin's disease may show the characteristic cellular proliferations of these diseases; and carcinoma may show neoplastic cells. Fibrosis, aplasia and so forth may be readily seen and Gaucher cells are quite easily recognized. From the standpoint of prognosis and possible therapy, it is important to discriminate between these conditions, and the sternal bone-marrow biopsy, whether performed by simple puncture — which is adequate in most cases — or by trephine, is pre-eminent in this regard. Myxedema should not be forgotten as a cause of refractory normocytic anemia, and I have seen a number of these cases treated for various blood conditions. Hepatic disease, particularly with splenomegaly, or various conditions in which splenomegaly is prominent — splenic-vein thrombosis, Gaucher's disease and even certain cases of hypersplenic hemolytic anemia — may result in pancytopenia. Splenectomy may be of definite value in such cases in restoring the blood picture to normal levels.

"Pancytopenia" is perhaps a better term than "refractory anemia" because it indicates simply that the cells in the blood are all reduced. In any event, one should realize that the finding of these hematologic abnormalities is merely a point of departure for further careful studies, which may include the marrow, the liver function, the basal metabolism, the urobilinogen excretion and so on. Pancytopenia, like anemia, is merely a symptom that requires clarification before a definite diagnosis can be determined.

The therapy of aplastic anemia, and in fact of most of the cases showing pancytopenia, — except those in which myxedema, splenic disease or increased hemolysis can be demonstrated, — is admittedly unsatisfactory. Vaughan⁵⁴ tried sternal bone-marrow transfusions in 4 cases of aplastic anemia with completely negative results. I have had similar experiences in both adult and juvenile aplastic anemia. Congenital hypoplastic anemia

of infancy and childhood is a definite entity in which there is a congenital failure of erythropoiesis. These children may be kept alive and well indefinitely by repeated transfusions. Splenectomy is of questionable benefit, but may be valuable if there is any evidence whatever of increased blood destruction. Kohlbr²⁷ found no effect from sternal bone-marrow transfusion. The value of this procedure,⁵⁸ in which a few cubic centimeters of normal sternal marrow admixed with blood is placed in a patient's sternal-marrow cavity, must be seriously questioned.

HEMOLYTIC SYNDROMES

Familial Types

A classification and a discussion of the mechanisms of the hemolytic syndromes were presented in last year's review.⁵⁹ In an American Medical Association exhibit, Dameshek, Greenwalt, Tat and Dreyfus presented in graphic form the physiologic, etiologic and clinical aspects of the various hemolytic syndromes, including the familial and acquired hemolytic anemias and the hemoglobinurias.* There are three types of familial, hereditary hemolytic anemias: spherocytic, Mediterranean target-oval-cell and (African) target-sickle-cell. The spherocytic type is familial; ordinarily known as congenital hemolytic jaundice, it responds well to splenectomy. The Mediterranean target-oval-cell syndromes (commonest in Italians and Greeks) vary greatly in their severity from the fatal Cooley's anemia to mild hypochromic anemia with target and oval cells.^{2, 60} One of their characteristic features is the presence of the target cell in increased numbers. Since these cells are thinner than normal, the hypotonic fragility test shows increased resistance. With the target cells are usually found varying numbers of oval or elliptical and heavily stippled erythrocytes. Despite the low color index, which is always present, these cases are completely refractory to iron therapy. They are important diagnostically since icterus, splenomegaly, anemia, stippling of the red cells and even heart murmurs are common. From the hereditary standpoint, they are of unusual interest since inheritance is Mendelian dominant in type, most of the progeny being affected. Of even more significance is the fact that the mating of two individuals with the mild disease may result in severe Cooley's anemia in one or more of the children.

Since target cells and increased hypotonic resistance are common in sickle-cell anemia, and since there are many other features of resemblance with the target-cell syndromes, the possibility was

*This exhibit has been reprinted in book form (*Hemolytic Syndromes* By William Dameshek, M.D., Tibor J. Greenwalt, M.D., Russell F. Tat, M.D., and Carlisle Dreyfus, M.D. 43 pp. Boston: The Bailey Press 1942.)

advanced that the Mediterranean target-cell disease might be related to the essentially African target-sickle-cell syndromes. Transitional forms between the two syndromes have been found. Heart murmurs, usually rough systolic in type, are noted in both conditions. In a young Negro child it is often difficult to determine whether the murmur is of rheumatic origin or due to the sickle-cell anemia. Spells of fever and joint pains are common in both conditions, and it is therefore necessary in every case to rule out sickle-cell anemia and the sickling trait. These points are discussed by Walker and Murphy⁶¹ and by Klinefelter.⁶² The former authors report an unusual case in which sickle-cell anemia was complicated by acute rheumatic heart disease. Klinefelter attributes all the cardiac findings in sickle-cell anemia to diffuse enlargement of the heart with resultant systolic and diastolic murmurs and prolongation of the PR interval in the electrocardiogram. Although he believes that the cardiac changes are secondary to the severe long-standing anemia, this often seems unlikely since the murmurs are often very striking and the anemia very mild. What is more, cases of severe hypochromic, hemolytic and pernicious anemia usually fail to show murmurs of such degree of severity.

Familial hemolytic jaundice should be differentiated from a familial nonhemolytic variety that was recently described by Dameshek and Singer.⁶³ Although the jaundice is familial, hereditary and acholuric, and associated with the presence of indirect bilirubin in the blood, there are no evidences of increased blood destruction. There is no splenomegaly, and the blood-cell and reticulocyte counts are normal. The bile-pigment output as measured by the fecal urobilinogen is low. Why, then, the jaundice? This appears to be due to a constitutional hepatic dysfunction, the liver cells being unable to remove bilirubin from the blood stream at a normal rate. Thus there seems to be a specific physiologic dysfunction in bilirubin excretion, since other liver-function tests are completely negative and biopsy of the liver is normal.⁶⁴ The incidence of this disorder is much higher than has been suspected. Many cases of mild jaundice probably fall into this category.⁶⁵ The importance of the condition lies in the fact that it is commonly mistaken either for familial hemolytic jaundice or for hepatic disease. Other than diagnostically, it appears to have no great significance, since a number of persons in these families have been known to reach old age.

Acquired Types

The results of splenectomy in the hemolytic crisis of familial spherocytosis are as a rule excel-

lent, but there is still disagreement regarding its value in the acute cases of the acquired groups. Thus, Sharpe and Tollman⁶⁶ in describing 5 cases of "refractory hemolytic anemia" found that transfusions produced dangerous and alarming reactions in 2 cases and that splenectomy in each case failed to modify the course of the disease. The latter statement is not borne out by the case reports. Thus, in Case 1 the patient slowly recovered after operation, whereas prior to it the course had been progressively downhill. Case 2 was obviously not one of hemolytic anemia (no anemia, normal reticulocyte count, direct bilirubinemia and so forth). In Case 3, in which the patient was desperately ill, there was prompt improvement in the blood and progressive decrease of the jaundice with slow but complete recovery. In Case 4, the diagnosis of hemolytic anemia must be considered as extremely doubtful, since there was no record of bilirubin estimation, the reticulocyte percentage was only 2.4 per cent, and the leukocyte and polymorphonuclear counts were very low. In Case 5, splenectomy was postponed until the hemoglobin percentage was 16, and the red-cell count 510,000! It was then performed as an emergency measure and the patient died shortly afterward. Thus of the five so-called "refractory cases" reported, 2 may not have been hemolytic anemia, in 2 the patient recovered, and in 1 procrastination may have been at least partly responsible for the poor result.

Jackson, Parker and Lemon⁶⁷ claim that some cases of "agnogenic" (idiopathic) myeloid metaplasia of the spleen masquerade as hemolytic anemia and that it is important not to remove the spleen because blood cells are being produced there. However, in hemolytic anemia it can be shown that the bone marrow is extremely hyperplastic in response to hemolysis and that myeloid metaplasia of the spleen and liver is a frequent occurrence. Brewster and Wollenman,⁶⁸ apparently accepting Jackson's viewpoint, have recently reported a case of acute acquired hemolytic anemia with spherocytosis in which splenectomy was unsuccessful. The myeloid metaplasia is stressed and the intimation is made that this case probably belongs in Jackson's group. I have seen marked myeloid metaplasia both of the spleen and liver in patients who have recovered after splenectomy, and this is not surprising in view of widespread regenerative activity in response to hemolysis.

My own conception of the value of splenectomy in acquired hemolytic anemia is based on a study of 18 splenectomized cases, of which 10 made full recoveries and 8 died.⁶⁹ Although this mortality rate is undoubtedly high, it included a number of procrastinated and desperate cases. In these cases, the high mortality with splenectomy (about 40

per cent) must be balanced against the almost certain 100 per cent mortality involved in the policy of "waiting for something to turn up." It is quite impossible in a given case to state categorically whether or not recovery will take place; however, it is unwarranted to withhold operation, which may prove dramatically successful. Temporization, which involves many transfusions, may result in irreversible hemolysis for which splenectomy is often valueless. If the patient fails to respond to two or three transfusions, splenectomy should be done.

One of the acquired hemolytic anemias in which splenectomy has no effect is that curious condition known as paroxysmal nocturnal hemoglobinuria. In this disease, there are chronic hemolytic anemia, persistent hemosiderinuria and paroxysms of nocturnal hemoglobinuria. The mechanisms are completely obscure. The red cells of this disease are unusually susceptible to hemolysis by dilute acid and the acid fragility test therefore becomes of great importance in the diagnosis of an acquired case in which hemoglobinuria may not be prominent. Both why the red cells are broken down in intravascularly (only in the kidneys?) and why hemosiderinuria is always present are mysteries. Experiments that may have a bearing on some of these points are presented by Yuile, Steinman, Hahn and Clark.⁷⁰ These authors noted a drop in the renal threshold for hemoglobin in dogs after repeated injections, together with dense deposits of iron staining pigment in the convoluted tubules—findings that are present in the above disease. These and other data are summarized in a review article on hemoglobinuria by Yuile.⁷¹

Methods

By the use of the Evelyn photoelectric colorimeter, it is possible to differentiate readily and quantitatively between the prompt (direct) bilirubin and the delayed (indirect) type. Lefebvre⁷² and Cantarow, Wirts and Hollander⁷³ have investigated these phenomena. Cantarow et al. recommend the quantitation in each case studied of both indirect and direct bilirubin, since if the direct bilirubin is increased either absolutely or relatively, it indicates some degree of hepatic impairment. The use of the bile pigment output, chiefly the fecal urobilinogen, and of the hemolytic index in the measurement of hemolysis is stressed by Miller, Singer and Dameshek.⁷⁴ These observers state that of the various indexes of possibly increased hemolysis—icteric jaundice, indirect bilirubinemia, an increase in the urinary excretion of urobilinogen, anemia and leukocytosis—no one is specific. An increase in the daily fecal output of urobilinogen or in the hemolytic index is, however, unequivocal evidence of an increased

breakdown of blood. The latter index relates the output of bile pigment to the total grams of circulating hemoglobin from which the urobilinogen is derived. Thus the output of 200 mg of daily fecal urobilinogen at a level of 5 gm of hemoglobin per 100 cc of blood represents three times as much destruction as the same output at a 15 gm level. This holds true for children as well. A male adult weighing about one hundred and fifty pounds excretes over 150 mg of urobilinogen. This amount in a fifty pound child represents about three times normal value. The urobilinogen output following transfusions of stored and fresh blood was studied by Wasserman, Volterra and Rosenthal.⁷⁵ The excretion of bile pigment after transfusion with stored blood was far higher than after transfusion with fresh blood, being directly proportional to the length of time of blood storage. Blood stored for more than seven days was so readily broken down that the authors concluded that its use was inadvisable in anemia. According to my own experience, the use of stored or bank blood, however fresh, should be reserved for hemorrhage or shock. For any of the so called 'blood dyscrasias'—whether concerned with the red cells, white cells or platelets—fresh citrated blood is best.

The osmometric behavior of normal human erythrocytes has been studied by Guest and Wing⁷⁶ by the use of an ingenious method in which the degree of actual swelling of the red cells under conditions of hypotonicity could be studied. These experiments indicated that normal human erythrocytes are perfect osmometers, that is, they behave mathematically correctly with reference to swelling in relation to the various hypotonic salt solutions. By means of a radioactive ion technic for tagging the red cells, Cruz, Hahn, Bale and Belfour⁷⁷ reached the surprising conclusion that old cells are far more resistant to hypotonic salt solutions than new cells (reticulocytes). This is contrary to what one might expect physiologically.

HEMORRHAGIC DIATHESSES

Lozner⁷⁸ states. "The body, when injured, possesses two main defenses against the occurrence of hemorrhage. These may be called the blood coagulability defense and vascular defense." The blood coagulability defense may in general be subdivided into two headings, comprising the platelets and the various chemical or enzymatic factors that are concerned in making blood clot when it is shed. Thus three main types of hemorrhagic diathesis may be discriminated: that which is associated with a disturbance in one or more of the chemical factors, such as calcium, thromboplastin, prothrombin, thrombin, fibrinogen, fibrin and antithrombin; that due to a deficiency or defect

of the blood platelets; and that secondary to a disturbance in the capillary walls. The first two may properly be grouped in the blood dyscrasias; the third is a vascular condition.

Methods

Ivy, Nelson and Bucher⁷⁹ describe a standardized cutaneous venostasis bleeding-time technic in which the skin of the forearm is used, venostasis being produced by a pressure of 40 mm. of mercury from a sphygmomanometer cuff. The normal mean bleeding time by this method was 61.56 (\pm 2.08) seconds. To control most of the known factors that influence the bleeding time, Copley and Lalich⁸⁰ devised a so-called "hemorrhagometer," in which the principle of bleeding into fluid kept constantly at 37°C. was used. In addition to the red-cell or blood flow, a whitish flow was observed, which was believed to be mostly lymph, and thus a "lymph time" was suggested. The normal bleeding time by this method was 170 to 180 seconds, which is quite comparable to the Duke bleeding time, in which a simple puncture of the ear is performed. Lozner, Taylor and MacDonald⁸¹ studied the effect of foreign surfaces on blood coagulation. Glass apparently has a definite effect in causing blood to clot rapidly, since the same blood in paraffin-treated or plastic (Lusteroid) tubes shows a far longer clotting time: that is, glass eleven minutes, paraffin forty-four minutes and plastic forty-nine minutes. This difference is probably due to the presence of negatively charged ions on the glass surface. It is fortunate that the capillary endothelial surfaces behave more like plastic than like glass. At any rate, the surface with which the blood comes in contact must also be considered in the blood-clotting problem.

Although Quick's method for determining prothrombin in the blood is almost universally accepted, modifications are constantly being published. It is true, as Quick himself stated, that his and other tests are based on an unproved assumption—namely, that they actually measure prothrombin—and "therefore the validity of the results which they yield can be judged only by correlation with clinical observation." Copley⁸² believes that the term "prothrombin concentration" may be inaccurate and says that the term "prothrombin time" is to be preferred. Cheney⁸³ presents a simplified plasma-coagulation time in which recalcification is carried out but thromboplastin (rabbit brain) is not used. He contends that the addition of thromboplastin is unnecessary and that the test is satisfactory for vitamin K deficiency provided the physical conditions of the procedure are closely adhered to. A "one-minute bedside prothrombin method" is described by Rhorer,⁸⁴ who states that it gives results quite comparable to other more difficult and

time-consuming tests. A large drop of blood is allowed to fall into the hollow of a suitable glass slide, following which thromboplastin is added and the coagulation time observed.

The failure of circulating blood to clot spontaneously in vivo still remains an obscure phenomenon, according to Wilson,⁸⁵ since all the elements essential for immediate coagulation in vitro are apparently present. Howell has consistently maintained that there is an antithrombic substance in the blood. This might be heparin. His views are summarized in his recent article.⁸⁶ Wilson describes a method for the determination of antithrombin in blood serum and plasma and finds that normal blood contains an average of 90 units of this substance per cubic centimeter. He states that the hemorrhagic tendency in hypoprothrombinemia is not fully explained on the basis of decreased prothrombin but that hemorrhage usually occurs when the prothrombin unitage approximates or is lower than the antithrombin unitage. Tagnon⁸⁷ describes a method for obtaining from oxalated plasma a proteolytic enzyme active in blood coagulation. This enzyme appears to play a primary role in the mechanism of blood coagulation and its absence may be the cause of hemophilia.

Bell, Lazarus and Munro⁸⁸ describe a standardized method for the determination of capillary fragility based on Gothlin's method of 1931 and similar to that worked out more recently in this country by Wright and Lilienfeld.⁸⁹ A circle is measured over the forearm and a blood-pressure cuff is inflated over the upper arm for fifteen minutes at 50 mm. The petechiae are counted with the naked eye. A petechial count below eight can be regarded as normal, whereas eight or more petechiae require further investigation. In women near the menstrual cycle and in individuals with diminished ascorbic acid levels, the petechial count may be increased. If these factors can be excluded, a high petechial count is definitely abnormal.

Clinical Features

Hypoprothrombinemia. Sanford and Shmigel'sky⁹⁰ studied in infants the question whether the presence of bile and food in the small intestine is necessary for the formation of prothrombin. They concluded that the present explanation of the synthesis of vitamin K by bacteria in the small intestine and the necessity of bile for its conversion is untenable. The liver appears to be the principal source of this vitamin and continues to form it independently of extrinsic causes until its functions are diminished by serious damage. The chemistry of vitamin K is fully (and readably) discussed by Fieser,⁹¹ one of the leaders in this field. A

rarity, namely a case of idiopathic hypoprothrombinemia in a boy of eighteen, is described by Rhoads and Fitz-Hugh.⁹² The case had previously been classified as an atypical one of hemophilia because of a persistent tendency to bleed. In another article on experimental hypoprothrombinemia, Rhoads, Warren and Panzer⁹³ state that a reduction of plasma prothrombin has been effected experimentally by at least ten different means, including modifications of the diet, the liver and the bile ducts, as well as through sweet-clover disease. Clinically, hypoprothrombinemia may be due to dietary K avitaminosis; to a conditional K avitaminosis secondary to the absence of bile salts from the intestinal tract and to liver injury of sufficient degree to prevent synthesis of prothrombin at an adequate rate. The latter condition does not respond to vitamin K therapy, the first one responds quickly, and conditioned vitamin K deficiency requires bile salts in addition to oral vitamin K.

The administration of vitamin K to women in or just before childbirth has been recommended as a routine procedure. It is well to remember that many newborn infants have a low concentration of prothrombin without presenting any evidence of hemorrhagic disease. If the concentration of prothrombin in the blood can be raised prior to the rigorous journey through the birth canal, it is probable that intracranial hemorrhage and its distressing sequelae can be largely avoided. Mull, Bill and Skowronska⁹⁴ recommend 1 mg. of the vitamin orally, four to ten hours before delivery. Most authors recommend the intramuscular injection of a vitamin K preparation during the first stage of labor, especially since gastrointestinal absorption by the mother may be subject to much fluctuation. Infants of mothers treated with vitamin K usually present a normal prothrombin time, quite in contrast to those from untreated mothers. Infants with clinical evidence of hypoprothrombinemia can be treated with 1 mg. orally at eight-hour intervals for a day.

Knowledge that the hemorrhagic sweet-clover disease of cattle is due to hypoprothrombinemia has led to a series of brilliant investigations, chiefly by Link and his associates of the University of Wisconsin, culminating in the synthesis of 3,3'-methylenebis (4-hydroxycoumarin). This substance, when given orally, produces a well-marked reduction in prothrombin and can thus be used to diminish the coagulability of the blood. Bingham, Meyer and Pohle⁹⁵ and Meyer, Bingham and Axelrod⁹⁶ report on the experimental and clinical aspects of dicoumarin administration. The substance is given orally in an initial dose of 5 mg. per kilogram of body weight, with daily doses thereafter of 1.5 mg. per kilogram. Since individual

responses vary considerably, it is necessary to control the prothrombin and coagulation times frequently. Cautiously used, dicoumarin may be of value in conditions with impending or active thrombosis or following splenectomy. Because of the ever-present possibility of hemorrhage (cerebral, renal and so forth) its present use should be limited to patients kept under carefully controlled observation. Administration of vitamin K will not correct the prothrombin deficiency induced by the drug.

The thrombic activity of a globulin fraction derived from rabbit plasma and the use of rabbit thrombin as a local hemostatic were described by Lozner, Taylor and Taylor⁹⁷ and were mentioned in last year's review. For local use, a square of saline-moistened filter paper is placed over the dry powdered rabbit thrombin (Lederle) that has been applied to the wound. This therapeutic procedure should prove of great value in the control of local bleeding and has even been found effective as a local application to bleeding surfaces. The treatment of the latter disease still remains unsatisfactory, however, chief reliance being placed on transfusions of blood. Johnson⁹⁸ points out that certain difficulties are involved in transfusions, namely the necessity of typing and cross-matching and the possibility of building up intragroup incompatibilities with repeated transfusions. Johnson used dry plasma from blood that had been processed within the first few hours after removal from the donor. Keeping blood for seven days before lyophilization resulted in a very definite reduction in its thromboplastic activity. However, dry plasma that had been kept for months at 5°C. showed no reduction in its clot-promoting property. The average dose of plasma used was 125 to 150 cc.; typing of the plasma was found unnecessary, even with unpooled plasma. Prophylactically, one of the most satisfying results of the use of lyophilic plasma was the elimination of the fear of dental extractions. Thus, a dose of 150 cc. of plasma given prior to extractions reduced the coagulation time to normal; following extractions, the sockets were packed with dry plasma. Almost complete rehabilitation of one patient with severe hemophilia was accomplished by the use of injections of 125 cc. plasma given weekly for three months.

A fascinating series of studies on a hereditary hemophilia-like disease in swine is reported by Muhrer, Hogan and Bogart.⁹⁹

THE SPLEEN

The spleen still remains an organ "full of mystery." Hints of its various functions may be obtained, however, by removing it or by studying it

in relation to various clinical conditions. Studies of splenectomized material by Singer, Miller and Dameshek¹⁰⁰ disclosed an intimate spleen-marrow relation, a definite influence of the spleen on the thickness of the red cells and a similar influence on blood destruction. Following splenectomy, the leukocyte and platelet counts almost always increase, indicating (with bone-marrow studies) that the spleen normally exerts an inhibitory effect on the bone-marrow production of these cells. Howell-Jolly bodies and nucleated red cells, especially in abnormal states, appear in the peripheral blood, suggesting an influence of that organ on denucleation of the red cells. The red-cell population becomes thinner, as evidenced not only by various measurements but by an increased hypotonic resistance and the presence of target cells. The red cells, in their various passages through the spleen, probably become thicker and thicker and thus more hypotonically fragile; with the spleen removed, this process is retarded and the target cell becomes evident. This was shown experimentally by Miller, Singer and Dameshek¹⁰¹ in dogs and guinea pigs. Cruz and Robschey-Robbins¹⁰² found that in splenectomized dogs made anemic by bleeding or by the injection of acetylphenylhydrazine, the number of normoblasts in the peripheral blood during the first phase of the regenerative period was four times greater than that in the nonsplenectomized animal. These findings were also suggestive of a spleen-marrow relation, the spleen appearing to have an effect on the maturation or delivery of the nucleated red cell. I¹⁰³ have discussed various facts and fancies relating to the spleen, including such concepts as "hypersplenism." Normal hypersplenism, which occurs when the spleen is enlarged for almost any cause — infection, congestion, cirrhosis of the liver or splenic vein thrombosis — usually results in leukopenia, thrombocytopenia and granulocytopenia, and often in anemia. Despite the low counts in peripheral blood, the bone marrow is hyperplastic; immediately following splenectomy, the leukocyte and platelet counts rise and remain elevated. These findings may indicate a hypernormal effect of the spleen on the marrow. Abnormal hypersplenism is present when for some unknown reason the spleen exerts an unusual effect on the marrow, with resultant hemolytic anemia or thrombocytopenic purpura. In the latter condition, despite the lack of platelets in the peripheral blood, the marrow is crowded with megakaryocytes, which, however, fail to produce platelets. Directly after splenectomy, the megakaryocytes show intense platelet production and the platelet count increases rapidly. If these interpretations of the relations of the spleen and the marrow are correct, they indicate the elab-

oration by the spleen of hormones that have effects on the centers of red-cell, white-cell and platelet production in the marrow. The evidence is as yet purely circumstantial and must await further investigation for complete proof.

Felty's syndrome has recently received increasing attention. This is a disorder in which marked rheumatoid arthritis, splenomegaly and leukopenia are simultaneously present. Lockie, Sanes and Vaughan¹⁰⁴ adhere to Felty's original concept that, owing to the chronic rheumatoid infection, the spleen becomes affected and the leukocyte count is lowered. The sternal marrow in their 2 cases showed slight myeloid hyperplasia, and the spleen chronic nonspecific splenitis. Steinberg¹⁰⁵ points out that the leukopenia and the secondary anemia characteristic of the syndrome are not due to bone-marrow depression, since sternal-marrow biopsies showed a hyperplastic marrow. As he states, it seemed plausible that the spleen may act as a barrier in not permitting the blood to receive these cells in sufficient quantities. Splenectomy was accordingly performed in 1 case with a marked and permanent effect in bringing the leukocyte count to normal. In a similar case seen by me, the patient's leukopenia and neutropenia were so marked that she was subject to numerous attacks of pyogenic infection. The leukocyte count averaged 1000, with approximately 10 per cent polymorphonuclear leukocytes. Splenectomy was performed with the idea of bringing the leukocyte count to normal, especially since the bone marrow was found to show extreme hyperplasia of the leukopoietic tissue. Following operation, the white-cell count returned to normal and further infections did not occur. The platelet count, which also had been somewhat depressed, rose to normal levels and the patient's menorrhagia was alleviated. The results in these cases are probably related to the very interesting concept of primary splenic neutropenia developed by Wiseman and Doan.¹⁰⁶ The essential condition in 5 cases was profound granulopenia, panhyperplasia of the marrow and splenomegaly and recovery after splenectomy. Varying degrees of combination of hemolytic anemia and thrombocytopenia purpura were encountered and also corrected by splenectomy. It was assumed that a single mechanism — hypersplenism — was responsible for the anemia, leukopenia and thrombocytopenia, since all elements were increased after splenectomy. Thus, one may group primary splenic neutropenia with hemolytic anemia and thrombocytopenic purpura; all of which may be due to abnormal hypersplenism, as stated above.

Until recently, most cases presenting splenomegaly were immediately called Banti's disease or splenic anemia. Whether any such condition as

postulated by Banti exists is greatly to be questioned. Cirrhosis of the liver, splenic-vein thrombosis or portal hypertension due to various causes may result in splenomegaly, anemia and leukopenia. Similarly, Gaucher's disease, Boeck's sarcoid of the spleen and Felty's syndrome, as noted above, may all result in anemia, leukopenia and thrombopenia that respond to splenectomy. Banti's disease and splenic anemia are best considered as "wastebasket" diagnoses reserved for those cases that have either been studied superficially or in which all other diseases have been excluded. In the last year or two, "agnogenic myeloid metaplasia," as introduced by Jackson, Parker, and Lemon,⁶⁷ has vied with Banti's disease as the diagnosis in many cases of splenomegaly. The contention inherent in this rather impressive sounding term is that the spleen may be the site, for no known cause (agnogenically), of active but ectopic bone marrow hyperplasia. That the spleen ever develops myeloid metaplasia independently, except in chronic myelogenous leukemia, is to be seriously questioned. Fibrosis, sclerosis or aplasia of the bone marrow, or its invasion by leukemia, lymphosarcoma, Gaucher's disease and so forth, may result in such extensive depletion of the normal bone marrow that various tissues attempt to take up the burden. This is customarily done by embryonically active hematopoietic organs such as the spleen and the liver, but such organs as the lungs and the adrenal glands may participate.

The end result of bone marrow displacement plus myeloid metaplasia in the spleen is often a blood picture characterized by normocytic anemia, leukocytosis with the presence of immature granulocytes, reticulocytosis and polychromatophilia, together with the presence of nucleated red cells. The blood picture (and the splenomegaly) may thus resemble chronic myelogenous leukemia, but the trephine bone marrow biopsy shows the true marrow condition, which is either that of fibrosis or of replacement by various abnormal cells. Polycythemia vera may terminate in a similar end picture frequently miscalled chronic myelogenous leukemia. Severe hemolytic anemia of the acquired type, particularly if it is of several months' duration, may also result in myeloid metaplasia of the spleen and liver. Jackson and his collaborators contend, however, that the metaplasia of the spleen may be inherent in that organ and that hemolytic jaundice, osteosclerosis, fibrosis of marrow and so forth, are simply accompanying rather than primary features. If this is the case, it would be indeed harmful, as these authors maintain, to remove the spleen or treat it by x-ray, since this organ is producing useful blood cells. Setting aside the matter of whether the splenic disorder is primary or not, it seems to me that a carefully done

sternal trephine bone marrow biopsy should help to settle this question. If the marrow is aplastic, fibrotic or invaded by foreign tissue, splenectomy should certainly not be performed; if, on the other hand, it is hyperplastic and the patient shows hemolytic anemia, removal of the spleen should be seriously considered. Reich and Rumsey¹⁰⁷ recommend biopsy of the spleen through the peritoneoscope in doubtful cases. They state that the presence of myeloid metaplasia definitely establishes the diagnosis of agnogenic myeloid metaplasia of the spleen. This is quite contrary to my views, as stated above, and also to some of Reich and Rumsey's own case reports. Thus in Case 2 when a bone marrow biopsy was finally done—after splenectomy—it showed fibrosis. In Case 3, there was slight jaundice and the red-cell count rose from 3,000,000 to 6,000,000 after splenectomy; this case might well have been one of hemolytic anemia. In Case 4, which showed myelocytes in the blood and an essentially normal marrow at puncture biopsy, the white cell count after splenectomy rose to 134,000 (!), which might well indicate that leukemia was present. Case 5, which presented a fairly typical picture of hemolytic anemia, was not splenectomized. At autopsy, the bone marrow was erythroblastic. Critical examination of these cases leads one to suspect that enthusiasm for a "new" syndrome may result first in calling many diverse types of cases examples of this condition, and secondly in withholding appropriate therapy like splenectomy, from certain others. That fibrosis of the marrow, particularly after polycythemia, occurs and is associated with a leukemoid blood picture and myeloid metaplasia of the spleen is quite certain. That the latter is ever primary is, however, questionable.

Primary neoplasms of the spleen are rare. I have recently seen a case of primary lymphosarcoma and one apparently of primary Hodgkin's disease of that organ. Pines and Rabinovitch¹⁰⁸ give a full report of a case of hemangioma of the spleen. An interesting neoplasm is that of hamartoma, as described by Sweet and Warren.¹⁰⁹ Here the spleen is the site of a neoplasm or neoplasms composed of new but normal splenic tissue.

The days when splenectomy was performed for almost any enlargement of the spleen have practically gone. Splenomegaly may be due to a large number of diverse conditions. In general, these are: infections (typhoid fever, malaria, syphilis, tuberculosis, Boeck's sarcoid and so forth); hyperplasias (leukemia, Hodgkin's disease, lymphoma and myeloid metaplasia); increased blood destruction (hemolytic anemias of various types); portal hypertension (cirrhosis of the liver and so forth); storage disorders (Gaucher's disease and so forth); and increased blood volume (polycythemia). Determination of the cause of the enlarged spleen in a

given case may be quite difficult, requiring careful and at times intricate studies of the blood, bone marrow and bones, the liver function, the serology, the esophagus (for varices) and so on. Puncture biopsy of the spleen, which is recommended by some workers as a harmless procedure and of considerable diagnostic value, should not be undertaken too lightly because of the danger of hemorrhage.

Splenectomy must be considered primarily from the physiologic standpoint and not from that of the degree of splenic enlargement. Some of the largest spleens are seen in cases of chronic myelogenous leukemia and polycythemia and in occasional cases of Hodgkin's disease; these are best left alone. Some of the smallest spleens may cause the greatest trouble, as in thrombocytopenic purpura and leukopenia.

Definite indications for splenectomy are severe fulminating thrombocytopenic purpura and severe acute or subacute hemolytic anemia. In both these conditions, it is presupposed that definite causes for the purpura and the hemolytic reaction have been ruled out. To procrastinate in either condition is to invite disaster, either from hemorrhage in the first instance, or from persistent hemolysis in the second. In mild cases of idiopathic thrombopenic purpura, splenectomy need not be seriously considered. There is a growing indication for splenectomy in severe leukopenia and granulocytopenia, provided various well-defined causes, such as leukemia (aleukemic), aplasia and Hodgkin's disease, can be ruled out by bone-marrow studies. As noted above, Felty's syndrome with marked leukopenia may be a perfectly good indication. This may also hold true in Boeck's sarcoid, Gaucher's disease and portal hypertension when one or several of the triad of thrombocytopenia, leukopenia and increased hemolysis are present to a marked degree. Whether the spleen should be removed routinely in cases of portal hypertension, particularly when the liver is thought to be normal (splenic-vein thrombosis and Banti's disease), is debatable. In an excellent article on the present status of surgery of the spleen, Pemberton¹¹⁰ states that splenectomy in Banti's syndrome "lightens the load that has been thrown on the liver by reducing the volume of blood entering the portal circulation, removes possible toxic substances originating in the spleen, removes the splenic factor in blood destruction and produces adhesions for the establishment of collateral circulation." ¹¹¹ I cannot, so optimistic, it must be admitted that: probably some justification for these studies. The end-results of a ten-year follow-up of a sufficient number of splenectomized patients, hyp

without hematemesis, are not yet at hand. Pending this, the ultimate value of splenectomy in this group of cases must be kept *sub judice*. Occasionally, the spleen should come out because its large bulk in a child actually interferes with locomotion and therefore with further physical development. I have had this done in cases of Gaucher's disease, Cooley's anemia and sickle-cell anemia, with results that have been, at least temporarily, excellent.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29061

PRESENTATION OF CASE

A forty-eight-year-old Polish garment worker entered the hospital because of abdominal pain and weight loss.

Four months before entry the patient developed a rather vague upper abdominal pain, which was most marked on pressure over a point midway between the xiphoid and umbilicus. The pain was usually relieved by drinking milk and aggravated after eating meat. The patient occasionally felt nauseated but seldom vomited. Laxatives at first relieved the pain, but after a few weeks even these proved ineffective. He also noted swelling of the abdomen and ankles, the latter being present in the morning as well as the evening. Three months before entry he was seen in the Out Patient Department, where physical examination revealed a somewhat distended but nontender abdomen. The liver edge was palpable on deep inspiration, and the upper level of liver dullness was percussed to the fourth interspace. The spleen was not felt. Normal peristaltic sounds were audible. There was questionable bilateral ankle edema. Examination of the blood was not remarkable, and both a barium meal and a barium enema were negative. A chest roentgenogram showed a high diaphragm on both sides, with linear areas of atelectasis in the lungs. The heart was transverse in position and not enlarged. The aorta was remarkably tortuous but showed no actual widening. During the next three months, despite extensive study, no diagnosis was established. On one examination shifting dullness in the abdomen was found. A bromsulphalein test showed 5 per cent retention of the dye in the serum. During the period of illness he lost 20 pounds. He denied diarrhea, tarry, bloody or acholic stools, dysuria, pyuria and hematuria. He had suffered with nocturia (two times) for several years. Because of the persistence of symptoms and the lack of a diagnosis, hospital admission was advised.

The family history was noncontributory. The past history was not remarkable, except that the patient had always consumed large amounts of wine and beer.

Physical examination on admission revealed a well-developed man who did not appear to be in great distress. He had obviously lost a great deal of weight. The edges of the tongue were smooth and somewhat redder than normal. Examination of the heart and lungs was normal. The abdomen was full, particularly in the right lower quadrant, where no mass could be felt but percussion demonstrated a localized area of flatness. In the upper abdomen, the rectus muscles were separated in the midline for a distance of 4 cm. There was tenderness in the left calf on palpation and on movement of the left ankle. The left leg was 32 cm. in circumference at the calf and the right 31 cm. The left foot seemed warmer than the right and the pulsation of the dorsalis pedis artery was stronger on the right than on the left.

The blood pressure was 165 systolic, 102 diastolic. The temperature was 98.6°F., the pulse 92, and the respirations 15. The temperature ranged between 97 and 101°F. and the pulse between 70 and 120 on the four succeeding days.

Examination of the blood revealed a hemoglobin of 74 per cent, a red-cell count of 4,500,000 and a white-cell count of 10,300, with 64 per cent polymorphonuclear leukocytes. The urine was normal. The stool was guaiac negative on three examinations. The blood Hinton test was negative, and another gastrointestinal x-ray series was negative.

A peritoneoscopy was performed on the third hospital day.

DIFFERENTIAL DIAGNOSIS

DR. CHESTER M. JONES: "Four months before entry the patient developed a rather vague upper abdominal pain, which was most marked on pressure over a point midway between the xiphoid and umbilicus." I suppose they mean tenderness that was increased by pressure rather than pain that the patient felt.

The physical examination apparently confirms the patient's statement that there was pain on pressure in the midabdomen. The examination also seems to indicate that the liver really was enlarged.

The high diaphragm by x-ray might have been due to the large liver or to abdominal distention. The linear areas of atelectasis probably meant old pulmonary infarcts.

"The patient had always consumed large amounts of wine and beer." I suppose that is an attempt to sell me a diagnosis.

According to the record it seems clear that what was at first believed that this patient had cirrhosis of the liver. But as the story develops there are many discrepancies so far as such a diagnosis is concerned. I am sure that I am not going to

able to give a diagnosis that will be any more than tentative, but there are certain facts I should like to point out.

There is no mention of rectal examination but something was felt in the right lower quadrant. Was a rectal examination done on this patient?

DR. TRACY B. MALLORY: Yes. The right lobe of the prostate felt harder than normal but seemed to be normal in size.

DR. JONES: Would you trust a statement of that sort, Dr. Colby?

DR. FLETCHER H. COLBY: Not entirely.

DR. JONES: Neither should I. One should state that rectal examination showed an asymmetrical prostate, the right lobe being harder than normal. Another point should be made—namely, that no rectal mass was felt outside the prostate; that is important.

So far as the x-ray films are concerned, the heart is transverse, and I shall pay no attention to it. There seems to be a suggestion of displacement of the small bowel from the right lower abdominal quadrant. Certainly the x-ray findings are not distinct nor do they appear to be helpful. One thing can be said: there is no evidence of intrinsic gastrointestinal disease. It is also important, if we have the right to make the statement, that no esophageal varices were demonstrated. I assume that, with two gastrointestinal series, varices were looked for and apparently not demonstrated. This is an oblique film, and I should not say that the stomach or duodenum is displaced, nor is the duodenal curve. At least there is lack of evidence of an extrinsic pressure defect around the stomach or duodenum. This is a good picture of the jejunum without any evidence of disease.

The story is short—apparently four months—and is entirely consistent with a new growth, either primary or secondary to what had hitherto been a silent cirrhosis. He had a tremendous loss of weight,—20 pounds in four months,—without much vomiting. To be sure it was probably due to a lack of food intake; but it occurred. The patient had a mass with vague gastrointestinal symptoms. There is nothing in the record that gives any clue concerning the nature of the pain. It is poorly described. One can say that neoplasm should be seriously considered. We are hard pressed to believe that it was ulcer pain. It was not relieved by the things that relieve ulcer—milk, soda and so forth. The statement that meat made the pain worse is curious.

DR. MALLORY: He evidently gave a confusing story, Dr. Jones. The record says, "A very confusing story but the point which on reiteration seems definite is that the present illness came on within the past year and consisted of a constant

aching pain just above the umbilicus that was worse after eating a heavy meal and not definitely relieved by milk."

DR. JONES: One can say that it is an atypical story. There is nothing characteristic about it, and this fact is against the diagnosis of peptic ulcer. There are no cardiorespiratory symptoms, a point worth something in excluding certain diagnoses. Another fact that should be pointed out is that for two years he had had nocturia, never having previously noted it. I gather there was more or less language difficulty and that it was impossible to get an accurate story.

On physical examination the patient was emaciated and showed definite evidence of deficiency disease, which was probably secondary rather than the cause of the symptoms. It was evidenced by a loss of weight, a smooth red tongue, and, possibly, the appearance of edema from time to time. The liver on examination was palpable on inspiration, and the upper edge was at the fourth interspace or fifth rib. The diaphragm was certainly high, and it is quite possible that this patient really had a big liver, but at the time of physical examination on admission to the hospital absolutely nothing is said about the liver so one has the right to be skeptical about the enlargement noted in the Out Patient Department. I am not at all sure the liver was enlarged. If it was, then it subsequently diminished in size. The spleen was not palpable at any time. There is a definite note made to that effect. From these films, so far as I can tell, it seems fair to say that the spleen is not enlarged. If this patient had cirrhosis of the liver, which I doubt, with the edema and ascites that are supposed to have been noted one should expect to have been able to demonstrate some enlargement of the spleen.

On admission there were other physical findings that may be of importance—namely, signs of thrombophlebitis in the left leg, with an area of tenderness, increased warmth and possibly some edema. There was evidence of tortuosity of the aorta and of arteriosclerosis. But I think these two factors do not need to interest us too much. There was no anemia of importance. At least on one examination the lungs and heart were normal. The urine and stools were normal, and a Hinton test was negative. The bromsulfalein test showed 5 per cent retention at the end of half an hour. In other words, the laboratory findings are not diagnostic or helpful. All the x-ray studies were reported to be negative and serve only to exclude disease rather than to make a diagnosis. Fever was present, without leukocytosis. If this patient had a thrombophlebitis it is possible that the elevation of temperature to 101°F. may have been

due to a local inflammatory process in the leg. It is curious that there was no leukocytosis. I am inclined to think that the fever was due in part to what was going on in the leg. If there was intrahepatic disease, that fact, regardless of the nature of the disease, would lead us to expect slight elevation in temperature from time to time.

With these facts, or near facts, and negative findings, how can one make a diagnosis? I do not believe it is possible. The important thing to do is to arrive at the decision of what to do, having excluded certain things. Cancer of the gastrointestinal tract seems unlikely. It is possible to have a small lesion of the colon, miss it on the x-ray films and have the liver full of metastases. We have seen such cases. However, there is no evidence that this is the case here. The stool was negative, and there was no evidence of occult bleeding. Everything is against gastrointestinal cancer. Again, so far as one can tell there is no evidence of pancreatic enlargement. A cancer of the pancreas, clinically, is unlikely, and I think it was not present.

Did this patient have cirrhosis of the liver? He had an alcoholic history and a palpable liver on one occasion, he was said to have had shifting dullness in the abdomen, and he had edema on a few occasions in the legs. If that story is true one must entertain the diagnosis of cirrhosis of the liver. One fact in favor of it is the indefinite gastrointestinal story, but against it are the demonstration of an enlarged liver at the second examination, the failure to demonstrate the spleen or esophageal varices and the absence of retention of dye. If edema and ascites are associated with cirrhosis, one would expect to get a more specific set of findings than are available here. Furthermore, there was no anemia, and usually the patient with cirrhosis that comes into the hospital is moderately anemic. Therefore, I think that the logical diagnosis is not that of cirrhosis. We have seen many cirrhotic patients in this hospital whose symptoms are not due to the lesions of the liver; such a cirrhosis in a sense may be called compensated and not the dominant part of the history. The cirrhosis here, if it was cirrhosis, was not the cause of the symptoms. If that is true, how can we explain them on the basis of the findings we have? I confess I cannot do it. The best I can do is to suggest that he had a malignant tumor that had not been located. There is one curious statement—namely, that there was no mass in the right lower quadrant but flatness and, I take it, an increased sense of resistance. That is the most that they could say on physical examination. We do know that he had signs of thrombophlebitis in the left leg. I believe that this patient had a malignant tumor.

It may have been retroperitoneal or lower abdominal, and there may have been metastases in the liver. I am sure the decision to explore this case by means of peritoneoscopy was advisable. If cirrhosis was found and nothing else, I do not understand the symptoms.

DR. MALLORY: You see no contraindication to the use of the peritoneoscope in this case, Dr. Jones?

DR. JONES: I think peritoneoscopy should be done. However, the incision should be made as high as possible above the umbilicus because there is the suggestion that something is not right in the lower abdomen and therefore one should keep as far away from this area as possible. My idea in examining this patient would be that one should try to establish two things: first, the presence or absence of liver disease and, second, to see what else there was in the peritoneal cavity. The risk of peritoneoscopy as I see it is minimal and one that has to be accepted to gain further information.

DR. EDWARD B. BENEDICT: Peritoneoscopy showed the abdomen to be so full of adhesions that no air space could be obtained. No implants or tubercles were seen on the adhesions. I could not examine the peritoneal cavity. I tried in two places, just above the umbilicus and then below, and encountered adhesions in both places.

CLINICAL DIAGNOSIS

Carcinoma of liver or peritoneum?

DR. JONES'S DIAGNOSIS

Malignant tumor (abdominal or retroperitoneal).

ANATOMICAL DIAGNOSIS

Tuberculous peritonitis.

PATHOLOGICAL DISCUSSION

DR. MALLORY: Although Dr. Benedict wisely desisted when he encountered adhesions, twenty-four hours following the peritoneoscopy it became obvious that fecal material was draining from the peritoneoscope wound. The patient was therefore taken to the operating room and explored. A generalized adhesive peritonitis was found, and biopsy of the omentum showed that it was tuberculous in nature. An effort was made to seal the point of perforation, which to date has been unsuccessful. The patient still has a draining fistula.

DR. JONES: Was there free fluid in the peritoneal cavity?

DR. MALLORY: No. Is it correct, Dr. Benedict, that we have had other cases of tuberculous peritonitis in which peritoneoscopy has been either difficult or impossible?

CASE 29062

PRESENTATION OF CASE

DR. BENEDICT: There was one in which I perforated the colon but recognized it right away. The patient was explored immediately, and the opening sutured. But in this case there was no fecal odor, and I know that I was not actually in the bowel. I knew the diagnosis as soon as I found so many adhesions; at least I was reasonably sure that it was tuberculous peritonitis.

DR. MALLORY: The one other type of case that would be equally dangerous would be a diffuse carcinomatous process with adhesions.

DR. BENEDICT: They never give any trouble. I have had a lot of those cases and have never encountered the firm adhesions that you do in tuberculous peritonitis.

DR. MALLORY: So I take it, that if you thought there was a real likelihood of tuberculous peritonitis you would not attempt peritoneoscopy.

DR. BENEDICT: Not if it was the adhesive type.

DR. JONES: I think it is interesting that the x-ray films apparently showed no distortion of the silhouette of the bowel anywhere, or displacement.

DR. MALLORY: After he knew the diagnosis, Dr. Schatzki reviewed the films taken at the time of the small-bowel enema and made this comment:

Restudy of the films of the small-bowel enema, after being informed about the findings at operation, show that more attention should, perhaps, have been paid several factors. The small intestines filled particularly easily. The loops of the small intestine were grouped in a somewhat too regular order and the tract was, perhaps, slightly shortened. The lower border of the small intestine appeared somewhat smoother and somewhat higher than that usually seen. No intrinsic lesion, however, was present. All these findings together should have made one wonder whether these findings were not consistent with an intraperitoneal chronic disease such as tuberculous peritonitis.

But even after knowing the diagnosis, he did not think that there was anything definite. He believes he might have suspected it.

DR. JONES: I should think one could explain the edema on the basis of malnutrition—that is, nutritional edema. Whether there was ascites at the time it was thought to be present is questionable.

DR. MALLORY: A few months before entry ascites may well have been present. At the time of operation, the peritonitis was the dry adhesive type.

A fourteen-year-old girl was admitted to the hospital because of severe abdominal pain.

Two weeks prior to admission, while at camp, the patient suffered with sharp pain in the left lower quadrant, which disappeared spontaneously after two days, without medical care. Approximately four and a half hours prior to admission she was suddenly seized with a similar, but severer, acute, knifelike, intermittent pain in the left lower quadrant involving a 5-cm. area just above and parallel to Poupart's ligament. A short time later the pain radiated to an area above the symphysis pubis. Her physician apparently administered morphine with only slight relief. At times there was a "heavy sensation" in both labia, and slight pain along the medial aspect of the left thigh. There was moderate urgency initially, but this disappeared. The patient had no chills but felt feverish. There was no nausea, vomiting, diarrhea, distention, bloody or cloudy urine or other urinary symptoms.

The family history was noncontributory. The patient was said to have been kicked in the left groin three years previously but suffered only local tenderness, which subsided within a few days. Three months later she was said to have had "catarrhal jaundice," which lasted two weeks. She denied sexual intercourse. Her menses had been normal except that one week before periods there was a slight amount of thick white discharge. The last menstrual period had occurred nineteen days before the present illness. Her cycle was twenty-eight days, and the menses lasted five days.

Physical examination disclosed a well-developed and well-nourished girl who held her left side and cried because of the pain. Examination of the heart and lungs was negative. There was only mild tenderness and spasm in the left lower quadrant, and apparently costovertebral-angle tenderness was not elicited. No masses were felt. There was a slight mucoid vaginal discharge. The inguina admitted two fingers. The cervix was firm and freely movable without associated pain. There was an oblong exquisitely tender mass in the posterior cul-de-sac, which seemed to be a part of the retroverted uterus. It was firm, smooth, movable and about the size of an orange, with a round superior pole that extended up to the left lower quadrant. The ovaries were not felt. Rectal ex-

amination did not contribute any further information.

The blood pressure was 110 systolic, 70 diastolic. The temperature was 100.4°F., the pulse 76, and the respirations 20.

Examination of the blood revealed a white-cell count of 20,500. The urine was normal. A stool was guaiac negative. A cervical smear was negative for gonococcus. A flat plate of the abdomen revealed no unusual soft-tissue masses or areas of calcification.

An operation was performed several hours after admission.

DIFFERENTIAL DIAGNOSIS

DR. GORDON DONALDSON: In this case I am afraid the x-ray films are not going to be of much help. I had hoped that the soft-tissue mass might at least be seen, and that we might even be able to see some radio-opaque areas within it. Perhaps Dr. Schulz can outline the mass.

DR. MILFORD D. SCHULZ: Any soft-tissue mass that may be here is indefinite. It would be "sticking one's neck out" to say that such a mass is present.

DR. DONALDSON: With the history of trauma to the left lower quadrant three years previously and with the pain running down along Poupart's ligament with inguinal distribution, I think we must at least mention the possibility of weakness of the abdominal wall or even an actual herniation. However, there was nothing on physical examination to support this suggestion. The urinary tract, too, with this type of radiation might be mentioned as the cause of this girl's pain. A badly prolapsed kidney in the region of this mass would, I should think, have been either atrophic or hydronephrotic by this time and there would have been some urinary findings, which we do not have. The only urinary symptom, moreover, was urgency. I shall also eliminate the gastrointestinal tract, since there was nothing in the history or physical examination to suggest such a lesion.

There is no note in the record of just when her catamenial life began, but I should guess that she had been having periods for a year and a half or two years. This is an ideal time for a hematosalpinx, but to have a large amount of blood in one tube, with the remainder of the genital tract functioning normally and with an undisturbed menstrual cycle, is most unusual.

A tumor of the uterus itself, such as a fibroid, should be mentioned as a possibility. In a young girl who had been menstruating for only a year and a half a fibroid of these dimensions is unlikely.

A tubo-ovarian inflammatory mass should also be considered, particularly since the mass was exquisitely tender. The patient did have a white-cell count that would go with an abscess in that location and she also had a vaginal discharge which was suggestive enough to make someone do a smear. However, there are some inconsistencies with this diagnosis: she was not sick enough, and the temperature and pulse were out of proportion to the white-cell count.

That brings us down to an ovarian tumor, such as a cyst, a fibroma or a dermoid. A tumor of the ovary that had twisted on its pedicle, thus cutting off its blood supply, is an adequate explanation for the elevated white-cell count, the degree of pain and the site of radiation of the pain, although one might have expected that the patient would also have had back pain. The local pressure that such a tumor would exert on the bladder accounts for the urgency and also for the mucoid vaginal discharge. This was probably a dermoid, inasmuch as dermoid is the most prevalent ovarian tumor in a girl of this age; however, I shall not go that far and shall just say that it was an ovarian tumor.

CLINICAL DIAGNOSIS

Twisted ovarian cyst.

DR. DONALDSON'S DIAGNOSIS

Ovarian tumor with twisted pedicle (? dermoid).

ANATOMICAL DIAGNOSIS

Twisted ovarian cyst.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The operation showed that this girl did have a cyst of the ovary. The ovary and tube had twisted on themselves four times, completely infarcting both organs. They were not adherent to surrounding structures, however. The cyst apparently was a simple one, since it contained clear serous fluid. It was not a dermoid. The infarction had completely destroyed its lining cells so that a more exact definition of its character is impossible.

EPIDEMIC KERATOCONJUNCTIVITIS

An epidemic of keratoconjunctivitis occurred among shipyard workers on the Pacific Coast in 1941.* Since then the disease has gradually spread eastward and has finally appeared in various cities on the eastern seaboard. From an economic standpoint it is of considerable importance, since it disables the worker from two to eight weeks and may seriously interfere with production in any plant where an epidemic takes place.

The etiologic agent is thought to be a virus, particularly since no pathogenic organisms have been

recovered from the conjunctival secretions. Scrapings from the conjunctiva show a preponderance of mononuclear cells. The incubation period is from seven to twelve days.

Symptoms consist of a foreign-body sensation in the eye, lacrimation, photophobia, swelling of the lids and enlargement of the preauricular and, sometimes, the submaxillary lymph nodes. There may be slight fever and general malaise. In the early stages the eye shows marked edema of the conjunctiva and the lids. The eye is watery, but there is little or no purulent discharge. After five to ten days there is an involvement of the cornea in from 40 to 60 per cent of the cases. This consists of small subepithelial infiltrates chiefly confined to the central zone of the cornea. The conjunctival symptoms usually subside in from one to three weeks, but the keratitis may remain active for many weeks. As a rule the disease runs a regular course that is little, if at all, influenced by any form of treatment. Since no specific therapy has been worked out, it is better to treat conservatively rather than overzealously. Cold compresses and mild soothing lotions and ointments afford relief, and atropine is indicated if the cornea becomes affected.

Transmission is by direct contact, contaminated hands, instruments, eyedroppers, towels and so forth, and the disease is communicable so long as the conjunctivitis is active. Affected patients should be isolated and should be carefully instructed in eye hygiene. Scrupulous care should be exercised by the physician and his attendants to avoid transfer of the infectious agent: the hands should be washed after examining affected eyes, and instruments and eyedroppers should be sterilized. Although not officially listed as a reportable disease, all suspected cases should be immediately reported to the Division of Communicable Diseases, Massachusetts Department of Public Health, to the Division of Occupational Hygiene, Massachusetts Department of Labor and Industries or to the Division of Industrial Safety, as is brought out in a letter published elsewhere in this issue of the *Journal*.

MEDICAL EPONYM

STELLWAG'S SIGN

"Ueber gewisse Innervationsstörungen bei der Basedow'schen Krankheit [Certain Disturbances of Innervation in Basedow's Disease]" were discussed by Professor Carl Stellwag von Carion (1823-1904), of Vienna, in an article which appeared in the *Vienna Medizinische Jahrbucher* (17: 25-54, 1869). A portion of the translation of his remarks after presenting his theory concerning the disturbances of innervation follows:

This peculiar pathologic relation is not simply an unrelated, curious finding, but occurs repeatedly in the disturbances of motility of the lids which are a constant feature in Basedow's disease. Examples are the abnormal wideness of the palpebral fissure, infrequency and incompleteness of involuntary closure of the lids, and failure of the upper eyelid to participate when the plane of direction of the eyes is elevated or lowered. . . . I have not found this second peculiar phenomenon (*infrequency and incompleteness of involuntary closure of the lids*) explicitly mentioned anywhere in the literature; yet in my observation, it is among the most constant and, indeed, characteristic eye symptoms of Basedow's disease.

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON MATERNAL WELFARE

ANALYSIS OF CAUSES OF MATERNAL
DEATH IN MASSACHUSETTS DURING 1941MISCELLANEOUS (*Concluded*)

During 1941, one death was due to poisoning from diethyl stilbestrol and sulfadiazine. This patient had diabetes. During her pregnancy she had had pyelitis, for which she had been given sulfadiazine; she was also given rather large doses of diethyl stilbestrol. Following her delivery, which was by cesarean section, she had an uncomplicated convalescence until she returned home. Recurrence of the pyelitis was treated by sulfadiazine. Persistent jaundice developed, which resulted in death. Autopsy showed a toxic hepatitis, acute pyelitis and acute nephritis with focal necrosis. This was a tragic disaster.

There was one death due to aneurysm. This patient had had one previous delivery. Her pregnancy had been uneventful until the onset of the fatal illness. The record does not state how far the pregnancy had advanced, but it is reasonable to infer that it was beyond seven months because cesarean section was performed

subsequent to laparotomy. The present illness developed suddenly while the patient was mopping the floor. She was said to have had a severe pain in the abdomen and collapsed. She was seen within half an hour and was immediately transferred to a hospital. On entry, the systolic blood pressure was 60, and the pulse 120 and of poor quality. Since the patient presented a picture of extreme shock, immediate laparotomy was decided on. The peritoneal cavity was full of blood, but no definite cause for hemorrhage was found; a cesarean section was performed, there being no statement concerning the condition of the infant. Death occurred twelve hours after operation. An autopsy showed a spontaneous rupture of an aneurysm of the splenic artery. This case illustrates the extreme value of post-mortem examination, without which no specific diagnosis could have been made.

One death was due to hydatidiform mole. This patient was a primipara who was first seen when approximately twelve weeks pregnant, because of bleeding. She was seen in consultation and kept in the hospital 12 days. The diagnosis of threatened miscarriage was made. The bleeding was scanty, and at the end of 12 days the patient was allowed to go home. Three weeks later she began to bleed profusely during the night and was sent to the hospital. On arrival, the pulse was 100. Two hours later a vaginal examination revealed grapelike masses in the vagina. The uterus was curetted, and the vagina was packed. Bleeding was excessive, and the patient died on the operating table. Had a correct diagnosis been made during the patient's first hospital stay and had the uterus been emptied at that time, it is likely that a fatal hemorrhage would not have occurred.

One patient died of psychosis. She was a primipara who was delivered by a cesarean section because of "cervical stenosis." She had lost 20 pounds in the last eight weeks of pregnancy. Following delivery the patient developed a psychosis and would not eat. The psychosis was manic in type, and death resulted from exhaustion and terminal bronchopneumonia, secondary to the psychosis.

One death was due to anaphylaxis. This patient had had eight previous deliveries, all the children being alive and well. She was known to have bronchial asthma, with a particular sensitivity to aspirin. She was delivered normally, and left the hospital seven days later. Two weeks after she had returned home she developed a cold and took some "special cold tablets." An asthmatic attack developed immediately and while being

sent to the hospital in a taxicab, the patient died. This was not a true obstetric death, but since it occurred during the puerperium, it must be so classified.

One patient died of cancer. This patient had three living children. In the fourth pregnancy she was sent to the hospital between the sixth and seventh months, complaining of tenderness in the right lumbar region. There had apparently been no prenatal care. A consultant found a mass in the left breast. At operation on the following day, a scirrhus cancer of the breast was found and the breast was removed. The patient died on the eighth postoperative day; the cause of death was listed as "carcinoma of the breast with carcinomatosis."

Five nonobstetric deaths that were reviewed have not been analyzed.

DEATH

COOK — WILLIAM W. COOK, M.D., of Quincy, died January 23. He was in his fifty-seventh year.

Born in Newcastle, Maine, Dr. Cook received his medical degree from Tufts College Medical School in 1910. He practiced in the Panama Canal Zone for ten years and then in Maracaibo, Venezuela. He was a member of the Massachusetts Medical Society, the American Medical Association and the American College of Surgeons.

His widow, three daughters, a son, a brother and a sister survive him.

CORRESPONDENCE

EPIDEMIC KERATOCONJUNCTIVITIS

To the Editor: A severe and highly contagious form of conjunctivitis, which has been given the name "epidemic keratoconjunctivitis," appeared among shipyard workers in California in September, 1941, and has already appeared in epidemic form in New England. Many doctors have undoubtedly never seen and possibly have never heard of this condition. There are sufficient data to indicate that the disease may easily be transmitted to uninfected persons under treatment for relatively trivial diseases or injuries to the eyes. Three of the four major outbreaks of this disease have occurred in large industrial groups.

The enclosed outline is being sent to physicians and others concerned, to give a clear idea of what to guard against, so that a serious outbreak of a disease which could interfere materially with our total war effort may be prevented.

PAUL J. JAKMAUH, Commissioner of Public Health

JAMES T. MORIARTY, Commissioner of Labor
and Industries

A. WILLIAM REGGIO, Surgeon (R), U.S.P.H.S.
Director, Medical Division,
Massachusetts Committee on Public Safety

GEORGE L. SCHADT, President,
Massachusetts Medical Society

EPIDEMIC KERATOCONJUNCTIVITIS

Causative Agent. Presumably a virus.

Incubation Period. Seven to twelve days.

Means of Transmission:

- (1) Direct contact.
- (2) Contaminated hands, instruments or towels.

Diagnosis:

- (1) Edema of one or both lids.
- (2) Moderately profuse lacrimation.
- (3) Acute follicular conjunctivitis (palpebral and bulbar conjunctivas are both involved).
- (4) Early lymph-node involvement, usually with swelling and tenderness of preauricular nodes.
- (5) Negative culture.
- (6) Development of pseudomembrane in conjunctival sac.
- (7) Smear of conjunctival scrapings shows mixed response, with predominance of mononuclear cells.
- (8) Development of corneal opacities (a late, not an early, development).
- (9) Opacities are small grayish areas below the epithelium, probably located in Bowman's membrane.

Course. In the early stages of the disease, diagnosis is difficult, and the early development of enlargement of the preauricular node should be watched for. The conjunctivitis usually persists ten days or longer, and the corneal opacities generally appear about as the conjunctivitis seems to be disappearing. The usual therapeutic agents are of little or no use, and no specific therapy is yet available. About 50 per cent of the cases develop bilateral involvement. The disease has been known to persist as long as eight weeks. In one epidemic, 85 per cent of the patients developed corneal opacities, and these appear to be permanent in the majority of cases.

Treatment. There is no specific therapy. Sulfonamide ointments and solutions have been used extensively. Cold compresses seem to produce more relief from discomfort than hot.

Recommendations:

- (1) Meticulous cleansing of hands and instruments by physicians, nurses and so forth.
- (2) Use individual eyedroppers.
- (3) Establish early diagnosis.
- (4) Isolation of infected patients.
- (5) Education of patients in measures of general cleanliness and eye hygiene.

Outbreaks of this disease, real or suspected, should be reported immediately to one of the three following agencies, from which further information may be obtained:

Division of Communicable Diseases
Department of Public Health

519 State House, Boston (CAP 4600)

Division of Occupational Hygiene
Department of Labor and Industries

23 Joy Street, Boston (CAP 0687)

Division of Industrial Safety
473 State House, Boston (CAP 4600)

Research in the epidemiologic and bacteriologic aspects of the disease is being carried on under the direction of Dr. Murray Sanders, Columbia University College of Physicians and Surgeons, 630 West 168th Street, New York City.

HAND-SCHÜLLER-CHRISTIAN DISEASE

To the Editor I regretted to see in the November 12 issue of the *Journal*, which I peruse regularly, that the eponym for the week [Schüller-Christian] left out the name Hand' from the condition that he was the first to describe. In fact I have always thought that Schüller added less than either Henry Christian or Dr Hand (who, by the way, is still practicing in Philadelphia) although together they did not give an adequate nosologic picture. Certainly Hand's description appeals to me as nearer the mark than Schüller's conclusions that are translated

E B KRUMHAAAR MD

The School of Medicine
University of Pennsylvania
Philadelphia

* * *

Dr Krumhaar's letter was referred to Dr Robert W. Buck, the author of the eponyms; his reply was as follows:

To the Editor I read with interest Dr Krumhaar's letter concerning Hand-Schüller-Christian disease. My original typescript regarding Schüller-Christian disease must have been written nearly ten years ago, at which time I knew nothing of the xanthomatosis. As Dr Krumhaar points out, Hand was as nearly correct as either Schüller or Christian. I think the proper eponym at the present time is 'Hand-Schüller-Christian, and I should include the descriptions of all three authors.

REPORT OF MEETING

HARVEY SOCIETY

At a regular meeting of the Harvey Society of Tufts College Medical School, held at the Beth Israel Hospital on October 23, Dr Harold W. Brown, dean of the School of Public Health of the University of North Carolina, spoke on the subject 'Intestinal Anthelmintics'. Formerly, the treatment of helminthiasis was based on erroneous reasoning, being aimed at disgusting the parasites with foul smelling, foul tasting medicines. Fortunately for the far flung armed forces of the United Nations in the present world conflict, who are stationed in areas infested with these parasites, knowledge is now based on scientific facts; however, it is still incomplete so that some methods of treatment are empirical.

The chief characteristics of the group of worms that infest the intestinal tract are as follows: they usually have a digestive tract, most of them have a low grade nervous system, they have no heart, there is a rudimentary excretory system and they have a horny outer layer of chitin that is like the substance forming a fingernail. It becomes obvious, therefore, that anything which affects such an organism must also be toxic to some extent on the host. Furthermore, these intestinal helminths vary in habits, anatomy, size and position, so that shotgun therapy is of no avail. For example the hookworm is small and cannot be affected until the bowel is cleaned, whereas the ascaris is large and is not easily protected by food. This is one of the reasons for the rationale of purges. Further reasons for the employment of purges are to rid

the host of toxins and to wash out worms that may only have been stunned by the anthelmintic.

Anyone concerned with the therapy of helminthiasis should be able first to diagnose the kind of worm responsible. This requires a fundamental knowledge of the various kinds of eggs.

The hookworm is a parasite about 1.0 cm long that has teeth which fasten onto the wall of the intestinal tract of the host, therefore the aim of treatment is to break this grip. Chloroform was once used, this drug does stun the worm, but it is liable to injure the liver of the host. One part of chloroform is soluble in 200 parts of water; hence much is probably absorbed from the intestinal tract. In an effort to find a solution of lower solubility and toxicity, carbon tetrachloride was employed. Since 1 part of this is soluble only in 2000 parts of water, there is less absorption from the intestinal tract of the host. A subsequent purge rids the alimentary tract of the stunned worms and further decreases the chance of toxic effects. However, this drug was found to have fatal results once in 30,000 to 50,000 cases, and even such a low mortality cannot be countenanced in public health work where the good will of the community is needed. This led to further research and to the discovery of the efficacy and nontoxicity of tetrachlorethylene. Since the solubility of this drug is only 1 part in 12,000, intestinal absorption is practically negligible. Furthermore, this compound is available and relatively cheap. The dose is 3 cc. Giddiness is an occasional complaint and rare cases of coma occur. Alcohol increases the rate of absorption and therefore adds to the danger of toxic reactions.

Although carbon tetrachloride has been supplanted in the treatment of hookworm disease, it is still the treatment of choice in tapeworm infestation. Injury to the liver apparently occurs only in the presence of low calcium and carbohydrate reserves. In suspected cases of deficiency, therefore the patient should be given a high milk high-carbohydrate diet for some time before the anthelmintic is employed. These parasites grow from the head and therapy is aimed at this part of the organism. The weight of the rest of the worm which often is 15 to 70 feet long aids in freeing the head by gravity, even if the worm is only stunned. If the body and not the head is obtained there is no advantage in attempting treatment again for about two months, since it is rare that the head can be dislodged without the beneficial effect of the weight of the body.

A combined infestation with round worms (*Ascaris*) and hookworms is not infrequent, and its management entails some difficulties. Both carbon tetrachloride and tetrachlorethylene stimulate the former, and in an attempt to escape, they are liable to enter the biliary tract or peritoneal cavity. Careful diagnosis obviates this danger. Oil of chenopodium, of which ascaridole is the active principle, is effective against this worm, but is of relatively high toxicity, death occurring about once in every 20,000 to 40,000 cases. There is often a question of idiosyncrasy to the drug. Experiments were carried out with the phenol and resorcinol derivatives in an attempt to find a compound that would be effective and at the same time nontoxic. Increasing the side chain decreased the toxicity to both worms and man and it was found that the most potent anthelmintic for this species that was relatively safe for man was hexylresorcinol. This kills 95 per cent of the worms and cures 90 per cent of patients. The dose is 1 gm. This drug precipitates protein and

forms a close bond with it, so food should not be given for five hours before or after treatment. Because of this property of protein precipitation, hexylresorcinol may affect the mucous membrane of the buccal cavity if taken by mouth in its native state. Gelatin capsules are usually used, but these are difficult for children to swallow.

Whip-worm (*Trichuris*) is not effectively combated by any single drug, although any of the usual anthelmintics kill a few. *Leche de higuero* (milk of the fig tree) is said to have been used successfully in Venezuela, but this is a particularly foul-tasting substance, of which a dose of 60 cc. is required. Its action is supposed to be due to fecin, a specific enzyme, which kills the worm by digestion. This enzyme has not been isolated.

BOOK REVIEWS

Principles of Extraperitoneal Caesarean Section. By James V. Ricci, M.D. 8°, cloth, 224 pp., with 47 illustrations. Philadelphia: The Blakiston Company, 1942. \$4.50.

This monograph, divided into eleven chapters, deals exclusively with the various modalities of the lower-segment cesarean sections.

In the first chapter, entitled "Gastro-Elytrotomy," the authors discuss the principles of extraperitoneal cesarean section and show, by an extensive review of literature, the various steps in the evolution of this operation. In the second chapter, which covers the period from 1906 to 1940, the intra-abdominal lower segment, exclusion and extraperitoneal types of cesarean section are elaborated. The appended bibliography, because of its completeness, is in itself a definite contribution to this subject. In the third chapter, the anatomy and histology of the isthmus and the lower segment, so necessary for a clear understanding of extraperitoneal approach in cesarean section, are lucidly described. The authors contend that the fully developed lower uterine segment originates from both the isthmus and the portio abdominalis of the cervix. The anatomy and histology of the fascia and its relation to the bladder, the lower segment and the peritoneum form the subject matter of the fourth chapter. This is well illustrated by means of line drawings and photomicrographs, and helps to visualize what takes place when these structures are separated from each other during the performance of extraperitoneal cesarean section. Chapter five covers incisions, scars and ruptures of the lower segment. Two types of incisions may be placed in the lower segment, the transverse incision and the longitudinal incision, both of which are discussed, their favorable and unfavorable points being brought out. The authors, who favor the transverse incision state, "In America, despite Phaneuf's contribution, DeLee's persistent advocacy of the longitudinal incision has retarded the adoption of the transverse lower segment incision." They show that Waters and Ricci have adopted the transverse incision in the true extraperitoneal cesarean section. Ruptures of the lower segment in subsequent pregnancies and labors are considered in detail. It is shown that most of the reported ruptures of lower-segment incisions followed longitudinal incisions. The methods of delivery in extraperitoneal cesarean section are treated in the sixth chapter, whereas in the seventh, wound infections and methods of drainage are elaborated. The authors advocate, whenever feasible, draining per vaginam. In the eighth chapter the technics of the extraperitoneal types of cesarean section are explained, and a concise table summarizing the various extraperitoneal technics adds to the value of the presentation. All methods of extra-

peritoneal approach are commented on, and four stand out: those of Latzko and Küstner, both with longitudinal incisions in the lower uterine segment, and those of Waters and Ricci, where the lower segment is incised transversely—the second Latzko operation in America is said to have been performed by James W. Markoe of the New York Lying-In Hospital. Because of the better exposure obtained the operations of Waters and Ricci are consistently gaining in favor in America and are supplanting those of Latzko and Küstner. The procedures of Waters and Ricci are well illustrated; they differ mainly in the method of the separation of the intact peritoneal sac from the bladder in exposing the lower segment. Chapter nine explains the essential factors in the execution of the Physick-Sellheim extraperitoneal cesarean section and is a recapitulation of the technical details elaborated in the previous chapters. The tenth chapter stresses extraperitoneal cesarean in patients previously cesareanized or laparotomized. By means of well-adapted illustrations, the authors show how the difficulty of adhesions may be overcome and how an extraperitoneal cesarean section may be repeated should the occasion arise. Finally, in the eleventh chapter, the operative and postoperative complications, which consist of injuries to the peritoneum and bladder during the dissection, are discussed in detail, and methods for the repair of these injuries are given. Fundal packing and hemorrhage are touched on, as are hematomas and retrovesical phlegmons.

The illustrations throughout this book are carefully chosen and well executed, and one is impressed with the tremendous amount of work required in the extensive compilation of the literature of lower-segment cesarean section. This monograph should prove to be of value to the obstetric specialist and should serve as ready reference for writers on the subject; whereas from a historical standpoint, it should interest all physicians who practice obstetrics.

The Management of Fractures, Dislocations and Sprains. By John A. Key, M.D., and H. Earle Conwell, M.D. Third edition. 4°, cloth, 1303 pp., with 1259 illustrations. St. Louis: The C. V. Mosby Company, 1942. \$12.50.

The appearance of the third edition of Key and Conwell's treatise on fractures and sprains marks an endeavor to produce an up-to-the-minute discussion of subjects than which there are scarcely any of greater importance. New methods are being introduced so rapidly that it is difficult to evaluate their comparative efficiency. Good results are obtained by old and outmoded methods. The important fact to remember is that each case is a law unto itself. There will inevitably be differences of opinion concerning the merits of different technics but, among them all, there will probably be at least one that may be applied to the condition in hand.

The methods set forth in this book are advocated by two authors whose opportunities for studying a large number of fractures and sprains have been extensive, and their opinions cannot be lightly brushed aside. For those who can hospitalize their cases of fracture, where it is possible to take advantage of all the modern facilities for dealing with these conditions, this volume should be of considerable value, since it outlines the authors' experiences in handling a large number of such lesions. One should remember, however, that facility in the employment of modern technics is the key to their satisfactory use. As a reference book for the guidance of such individuals this volume has much to recommend it, although in the management of some types of fracture

there will be divergences of opinion regarding the propriety of certain of the suggestions offered

It is unfortunate that the book is so bulky and heavy which interferes with its convenient use

Administrative Medicine Edited by Haven Emerson MD 4th, cloth, 839 pp., with 39 figures, 82 tables and 16 charts New York Thomas Nelson and Sons, 1941 \$7.50

This book should convince the most skeptical that administrative medicine is worthy of being considered a medical specialty or specialties Dr Emerson's long association with practically all types of medical, medico-social and public health activities has enabled him to develop a comprehensive collection of subjects and to select writers who were not only familiar with their subjects but also forward looking and future minded

The same general plan is followed in presenting each subject First, a short historical sketch of its development, next, a consideration of the present organization and activities, with indications of the trends and then in some cases, definite suggestions concerning future developments

The book is divided into three parts Part I deals with the organized care of the sick, hospitals of all kinds convalescent homes, outpatient service, home care, visiting nurse service and, finally, the latest development, voluntary hospital-care insurance Each author is a master of his subject Part II discusses public-health services International, national, state and local public health organizations are clearly delineated Then follows a series of interesting chapters on what might be termed the public health specialties—vital statistics, communicable disease control, occupational hygiene, milk control and laboratories, to mention only a few Persons who believe themselves well informed will learn much by reading these chapters Part III covers inclusive medical care for prevention and treatment The description of the medical services of the armed forces is particularly complete and clearly set forth, but under the stress of war probably is now undergoing marked changes

The chapters Medical Services under Government Auspices in the United States and Canada and Economic and Social Aspects of Administrative Medicine are complementary, the first setting forth the present stage of development of governmental participation and the latter presenting the arguments for future developments along the line of compulsory health legislation

This book should be most useful as an authoritative, up-to-date encyclopedia on the subjects presented

The Modern Attack on Tuberculosis By Henry D Chadwick, MD, and Alton S Pope, MD 8th, cloth 95 pp., with 5 illustrations and 8 tables New York The Commonwealth Fund, 1942 \$1.00

With the steady decline in the morbidity as well as the mortality from tuberculosis the time has come when the final attack for its complete eradication must be planned with vigor and determination It is with this thought in mind that this book has been written The authors state in their preface that they make no pretense of adding to the sum total of knowledge concerning tuberculosis They believe that sufficient facts are already available to make the eradication of tuberculosis a possibility within a few generations if the established techniques are effectively applied The writers are men of many

years of experience both in the clinical as well as in the public health field and thus can speak with authority and in sure judgment

The worthwhileness of this book is enhanced by its clarity and brevity This small book, divided into six chapters is crammed with information and important facts regarding the final triumph over the age old scourge of tuberculosis The authors' emphasis is centered on the prompt discovery of tuberculous infection and the early segregation and treatment of cases Case finding in the community is the modern watchword of the health worker Although early diagnosis was the goal of the tubercle worker twenty five years ago, his modern counterpart goes out into the field and searches for latent foci of infection in the most susceptible portion of the community Thus the authors urge mass x-ray examinations of tubercles—especially embryo physicians and nurses, patients in prenatal clinics, all contacts and elderly persons They also stress the sanatorium as not only the place for the treatment but also the place for the segregation of infected persons Thus they plead for more sanatorium beds in more attractive surroundings with greater appeal to patients The authors dare to prophesy that the bells that ring in 2000 may sound the death knell of the tubercle bacillus

The scientific and the public health aspects concerning the eradication of tuberculosis are clearly and authoritatively covered in this book It should serve as a useful guide not only to tuberculous workers but also to all interested in community health

Internal Medicine in Old Age By Albert Mueller Deham, MD and S Milton Rabson, MD 8th, cloth, 396 pp., with 10 illustrations Baltimore The Williams and Wilkins Company, 1942 \$5.00

The authors of this book, after a brief discussion of certain general aspects of old age, present internal diseases system by system, as they occur in the aged In consequence of this chosen limitation, two important features of practice among the old—psychologic problems and problems on the border line between medicine and surgery—are omitted In the present state of knowledge of geriatrics, the field should be covered for the practitioner relatively simply Authors of books of this sort however, err in including too many individual diseases concerning certain of which there is nothing of consequence to be said For example, in this book there are discussions of scurvy, agranulocytosis, amebic dysentery and Weil's disease that will not help the physician who deals with the aged as much as those in any standard textbook of medicine Moreover, in this book the authors often recommend treatment that is unacceptable to many physicians in this country transplutinin in pneumonia, creolite, guanacol and tuberculin in tuberculosis, iodides in arteriosclerosis neoraphenamine in coccal or mixed infections of the bladder, interdiction of meat and limitation of other proteins in impending hepatic failure and so forth There is much insistence on the weight of individual experience in rendering judgment on the efficacy of treatment, a form of argument that is least convincing to the critical mind Physiologic mechanisms, such as those of angina pectoris and hypertension, are described but with serious inaccuracy On the other hand, anatomic changes are more richly and more satisfactorily presented than in other available books in this field. It is only for this feature that the book can be recommended

Immunity against Animal Parasites. By James T. Culbertson, B.S., A.M., Ph.D. 8°, cloth, 274 pp. New York: Columbia University Press, 1941. \$3.50.

This monograph by a member of the Department of Bacteriology of Columbia University satisfactorily replaces the second edition of *The Immunology of Parasitic Infections*, published in 1929 by another expert in the field of animal parasitology.

It is divided into three parts. The second part, which deals with immunity in specific diseases, makes up the bulk of this book. With Taliaferro's classic textbook as its point of departure and citing almost all the significant papers issued after 1929, it gives thorough information on natural and acquired immunity against animal parasites.

The third part, consisting of only three of the twenty chapters, will be welcomed by the general practitioner who wants a review of vaccinations and diagnostic tests that are of recognized value.

The first part, although presupposing a knowledge of microbiology, is highly useful for it gives a general introduction to and the fundamental principles of the subject. With a few exceptions, for instance, the form of resistance called "premunition," studies on the mechanisms involved in immunity against animal parasites follow a path that is identical with the one opened up by investigations concerning immunity against pathogenic bacteria. Even ablative antibodies, which have been demonstrated by Taliaferro in immune serums against trypanosomes and by Campbell in immune serums against cestodes, trace their origin to antibodies uncovered in immune serums against anthrax and swine erysipelas. They have also been called "azygots" in order to point out their lack of absorption by homologous antigens. Culbertson, although conceding that ablative antibodies are not absorbable, maintains that their effect is due to their union with the antigens of the parasites. Considering the effort required to gather the heterogeneous literature on this matter, such a logical incompatibility and a few other discrepancies are quite understandable and do not affect the usefulness of this able attempt to give thorough orientation in a specialized branch that had to be worked out in a form accessible to the student, as well as to the practicing physician or veterinarian.

The illustrations, charts and tables have been selected with a didactic flair that will be appreciated particularly by the teachers, who henceforth will have at hand a treatise that they can resort to when lecturing on immunity against animal parasites.

The Principles of Anatomy: As seen in the hand. By Frederic Wood Jones, D.Sc. (Lond., Adelaide and Melbourne), F.R.S., F.R.C.S. Second edition. 8°, cloth, 418 pp., with 144 illustrations. Baltimore: The Williams and Wilkins Company, 1942. \$7.50.

The first edition of this well-known work, published in 1920, was prepared during World War I as part of the course of instruction to officers of the Royal Army Medical Corps to qualify them to care properly for military injuries of the hands. This second edition, similarly a product of war, is brought to date by the addition of six new chapters and twenty new figures in the text.

The author emphasizes topographical and functional anatomy, and uses the hand as an example of an anatomical method that can be applied to other regions. Beginning with phylogenetic and morphologic considerations of pentadactylism and polydactylism, he discusses the comparative digital, phalangeal, metacarpal and carpal formulas of

man and of other animals. Similarly he deals with flexure and cleavage lines, papillary ridges, nails, functions, fascias, bones, joints and sesamoids of the hand. In his study of morphology of the extrinsic and intrinsic musculature, he quotes Dwight's cautioning stricture that "to find in man an occasional form of a muscle that is normal in no matter what animal" does not necessarily explain "how the peculiarity could have been transmitted." Finally he gives in detail not only the vascular and lymphatic channels and arteriovenous anastomoses of the hand but also its somatic and autonomic nerves and the sensory and motor pathways that connect it with the brain. His method is illuminating, his observation accurate, his descriptions detailed, his interpretations conservative. Particularly valuable are his analyses of "trick movements" following nerve injuries.

As a text of applied anatomy, combined with such a clinical work as that of Kanavel, this book is of timely value to military surgeons preparing to treat war injuries of the hands. It is provided with many admirable illustrations and with well-selected references for further reading.

Castor Oil and Quinine: Once a doctor, always a doctor. By George W. Vandegrift, M.D. 8°, cloth, 252 pp. New York: E. P. Dutton and Company, Incorporated, 1942. \$3.00.

This is the biography of a New York physician who practiced from 1879 onward on the lower East Side of the city. The story is written by his son, presumably from authentic evidence received from his father. The elder Vandegrift was a typical "corner doctor." He soon established himself at the junction of two well-known streets, and treated everybody who came to his door for any sort of an illness. It was a rough sort of practice, but the art of medicine has seldom been better exemplified than in the story of this untutored, honest practitioner. The book gives the story of medicine as practiced in a big city and in a ward filled with Irish and German immigrants during the latter quarter of the nineteenth century. Vandegrift's account of his father is interesting and readable, and in many ways may be considered a unique document. The title gives the clue to the type of medicine practiced by this pioneer physician, for he, indeed, was as much of a pioneer as the man who went into the Far West during the early days of the century.

The Care of the Aged: Geriatrics. By Malford W. Thewlis, M.D. Fourth edition, thoroughly revised. 8°, cloth, 589 pp., with 50 illustrations. St. Louis: The C. V. Mosby Company, 1942. \$7.00.

In this edition, as in its predecessors, the author gives some consideration to the practical handling of most of the medical problems of old age. Unfortunately, knowledge of the fundamental characteristics of the aged, which must determine special aspects of their treatment, is fragmentary. As the title indicates, a summary of even this incomplete knowledge is outside the scope of the book. Hence, the uncertainties of geriatrics and the fundamental problems that await clarification and solution receive little emphasis. Furthermore, the book seems to slight the psychologic aspects of disease and treatment in old age. Since the author undertakes to deal with a wide range of diseases, it is to be expected that specialists will disagree with his advice in not a few instances. Nevertheless, the practitioner will find this the most helpful book in the field.

VASCULAR AND NEUROLOGIC LESIONS IN SURVIVORS OF SHIPWRECK*

I. Immersion-Foot Syndrome Following Exposure to Cold

COMMANDER JAMES C. WHITE (MC), USNR

BOSTON

As a result of enemy submarine activity, many survivors of torpedoed vessels have been exposed to unusual physiologic conditions. These include cold air and water and, when rescue is long deferred, prolonged dependency of the legs, malnutrition and vitamin deficiency. Many of these men have required hospitalization in naval and marine hospitals. One of the commonest in incapacitating lesions is painful swelling of the feet and lower legs. This condition has been called "immersion foot." It has been my privilege to study it in Scotland and along the western Atlantic seaboard from Nova Scotia to Virginia. A surprising feature is that painful swelling of the lower extremities may take place both after exposure to the cold of the North Atlantic winter and the warmth of the Gulf Stream in southern latitudes in April and May.

The purpose of this paper is to point out that in the true immersion foot syndrome, which occurs after relatively brief exposure of the lower extremities to cold water, there is actual thermal injury to the skin and subcutaneous tissue, whereas in the survivors of prolonged exposure in southern waters this feature is not present, but the painful swelling of the dependent parts is caused by a systemic disturbance.

CLINICAL OBSERVATIONS

Immersion foot, caused by prolonged chilling just short of actual freezing, has not heretofore received adequate recognition, although it must have occurred after torpedoings in the last war and after shipwreck in northern waters since time immemorial. An excellent clinical picture has recently been given by Webster, Woolhouse and Johnston,¹ the Canadian naval medical officers who have treated by far the largest number of cases. According to them:

At the time of removal of the patients from the open boats or rafts, the feet were cold, swollen and waxy

white in color, with scattered cyanotic areas. The patients complained at that time that their feet felt heavy, 'woody' and numb, and the feet were anesthetic to pain, touch and temperature.

Shortly after removal of the feet from this traumatic environment, the swelling increased rapidly as the feet became red, hyperaemic and hot without sweating, and the pulse in the vessels of the feet was full and bounding. In those more severely damaged areas—usually the toes, the distal part of the dorsum of the foot and the ball of the foot—the parts remained oedematous and hot, and assumed a livid, cadaveric appearance. A number of these latter areas later produced blebs, some of which were filled with straw-colored fluid and others with extravasated blood, and areas of ecchymosis commonly appeared over the medial aspect of the first metatarsophalangeal joint and on the medial aspect of the longitudinal tarsal arch. Many of these feet presented the appearance of incipient massive gangrene. The rapid swelling and increasing redness, accompanied by the extreme rise in temperature of the part, presented the picture of an intense vasodilatation, accompanied by definite damage to the vascular wall with transudation, as manifested by bleb formation and extravasation of blood.

The anaesthesia followed a variety of patterns. In the mildest cases these areas extended around the margins of the foot and over its plantar aspect, being of greater extent along the lateral border, where the mass-to-surface ratio is smallest. In the more severe cases these areas extended over the entire dorsum of the foot, and in some cases over the lower two thirds of the leg. Patches of anaesthesia over the knees in the prepatellar and infrapatellar regions were observed in two cases where there had been prolonged kneeling in the lifeboats.

Attention was first focused on this syndrome by the Medical Corps of the Royal Navy after the loss of a ship off the northern Norwegian coast in the late spring of 1941. The ocean temperature was around 40°F. A number of the crew were adrift on Carley rafts for several days. These rafts are large, doughnut-shaped floats with an open lattice in the center. The occupants are therefore forced to sit on the floating outer hull and keep their feet immersed in the cold water that washes in

*Released for publication by the Division of Publications, Bureau of Medicine and Surgery, United States Navy.

and out of the bottom. After these survivors were rescued by trawlers (which carry no medical officers), the mistake was made of rapidly warming their numb and swollen feet before the galley stove. Three months later, when I visited the naval hospital at which they had been treated, the last of these patients was being discharged. From the description given me by Surgeon Rear Admiral Sir William Wheeler and from the recently published account by Ungley,² the vascular and neurologic changes in the immersed extremities were identical with those of the Halifax survivors that are described below, except for their greater severity. Owing to the unfortunate rapid warming before the galley stove, a number of these men developed gangrene, which necessitated amputation. The others suffered from trophic disturbances of the skin and neuritic pain, which prevented their return to active duty for a very protracted period. The severity of the process and the prolonged period of convalescence illustrate the need of efficient first-aid and subsequent hospital treatment.

During the past winter over 100 similar cases have been treated in Halifax. Through the kindness of Surgeon Commander D. W. Johnstone, the senior medical officer of the Canadian Navy there, I was given every facility to examine 32 survivors of three vessels torpedoed in the North Atlantic early in March, 1942. These patients were under the charge of Surgeon Lieutenant Commander D. R. Webster, Surgeon Lieutenant F. M. Woolhouse and Surgeon Lieutenant J. L. Johnston, who were extremely co-operative and helpful. A description of their cases has just been published by them.¹ The reason for presenting this brief résumé of their work is twofold: first, to add observations on 15 other cases seen at the Halifax Infirmary, with the senior surgeon, Dr. Alan Currie, at the Columbia Medical Center, with Dr. David Bull, and at the United States Naval Hospital in Chelsea; secondly, to contrast these cases of immersion in cold water with a series of superficially similar, but fundamentally quite different, results of more prolonged immersion in warm water seen at the United States Marine Hospital in Norfolk during May, 1942. The latter group will be taken up in the second part of this paper.

The 32 patients seen in Halifax were exposed to air and water close to freezing temperature in three lifeboats for periods ranging from twenty-seven hours to four days. In all cases it had been impossible to keep the boats bailed dry, so that water was sloshing about over the floor boards from a depth of a few inches up to the height of the thwarts. The men's legs were therefore con-

stantly wet below the knees and actually immersed most of the time from the ankles down in cold water. The reaction of the lower extremities to cold and wet was greatly aggravated by the fact that they were continually dependent and that, on account of crowding, there was no opportunity to exercise or elevate the legs (see below, section on "General Responses of Tissues to Cold"). Whether the survivors wore shoes or not made little difference, as the wet feet became so swollen that any boot soon became tight and constricting. The feet under these conditions rapidly became numb, painless and cadaveric in color. A few of the men tried at first to keep out of the water, but soon gave up. Only in the rare cases where men had on loosely fitting rubber hip boots and managed to keep their feet relatively dry, or where they were able to wrap them in a blanket and keep them clear of the water for the better part of the time, were they able entirely to avoid this condition.*

On being picked up by rescuing vessels, those who suffered from immersion foot observed that it felt as though they were "walking on air" or "on blocks of wood." The more severely afflicted men could not maintain their balance or walk, and had to be supported or carried. On arriving in warm quarters below decks, their feet were so swollen that if boots had been kept on they usually had to be cut off. The extreme swelling and gray, cyanotic hue of the severe cases made it look as though many might develop gangrene of the feet. Fortunately, the mistake made in the first-aid treatment of the British survivors reported above was not repeated here. None of these men had their numb feet soaked in hot water or warmed before a galley stove. Some had them immersed in cold water for a brief period, others rubbed with alcohol (even this was a mistake; see below, section on "Treatment"). They were then put in bunks and given hot drinks. In the milder cases the feet began to tingle and burn as soon as they warmed up, but those more severely chilled remained numb for much longer periods.

On reaching Halifax it was observed that the feet, which at the time of rescue had been cadaveric in color, cold and numb, were pink, hot and painful, as in erythromelalgia. The edematous skin was dotted with petechial hemorrhages and, in the severer cases, with large blisters that resembled those of a superficial burn. Sensation,

*Since this article was written I have had the opportunity of examining 8 members of the crew on a torpedoed merchantman after three days adrift in cold water. Three of these men had been protected by a new type of rubber lifesuit and suffered no thermal injuries, whereas the remainder who wore ordinary clothes, all developed immersion foot of moderate severity.

which at first was absent above the ankle, usually descended to the midfoot within a period of twenty-four hours, although the toes often remained anesthetic for a period of several weeks (Fig. 1). With the partial return of sensation,

tion secondary to epidermophytosis eventually necessitated their amputation. Eight patients showed edema, blebs, petechiae and superficial patches of gangrene from their severe chilling (Cases 2, 3, 4, 6, 7, 8, 18 and 19). Thirteen men (including all

Moderate hyperemia and anesthesia, without much cutaneous injury, 2 weeks after rescue.
 Appearance of feet: Redness of skin and petechial hemorrhages
 Redness most striking in dependency Very slight residual swelling. Superficial loss of epithelium on soles
 Arteries: All pulsations strong
 Veins: Very prominent
 Sweating: Began slightly over skin of proximal feet at 13 days
 Neuritis: +++, beginning to subside

FIGURE 1 Case 10

burning, tingling pain became intense and, together with the risk of the blebs' rupturing and becoming infected, presented the major therapeutic problem. These clinical findings seen in the Halifax cases are summarized in Table 1 and illustrated in Figures 2 and 3.

Examination of Table 1 shows that of the 19 acute cases of true immersion foot examined in detail, only 2 developed areas of gangrene of sufficient depth to require surgery. In Case 19 bilateral major amputations were necessary, owing to the cellulitis that followed the prolonged severe exposure and was already present when the patient reached the hospital. The infection entered through the blisters that always develop after long immersion in cold water. In Case 1 the loss of tissue involved several of the small toes, and late infec-

tion secondary to epidermophytosis eventually necessitated their amputation. Eight patients showed edema, blebs, petechiae and superficial patches of gangrene from their severe chilling (Cases 2, 3, 4, 6, 7, 9, 10, 11, 12, 13 and 18), particularly in the first two weeks. At the

end of this period the active inflammatory process was usually subsiding, and the skin of the sole and toes desquamating in large sheets. In cases with inadequate early treatment, both swelling and

surgeon-general of Napoleon's army in the winter retreat from Moscow. In the Crimean War⁴ it was observed that the soldiers suffered most in temperatures just above freezing in the wet mud and

FIGURE 2 Case 1

The photographs were taken on the twelfth day after rescue. The man had been in a lifeboat without shoes for four days in the North Atlantic in March. The temperature of the sea water was recorded at 34° F., and his feet had been wet most of the time. On arrival in Halifax the hyperemia and vascular engorgement of the lower legs were intense; his feet were greatly swollen, blistered and anesthetic; his toes were blue-black and gangrenous looking. After treatment by cooling for twelve days in ice-packs, the swelling was greatly reduced, the blebs had nearly absorbed, and the condition of the toes was distinctly improved. Nerve recovery had not progressed far enough to cause pain.

pain tended to persist and become a cause of prolonged disability (up to six months).

A number of late complications have been observed in consultation with Drs. A. W. Stearns and R. S. Schwab at the United States Naval Hospital in Chelsea, and with Dr. D. C. Bull at the Columbia-Presbyterian Medical Center in New York City. These include atrophy of the intrinsic muscles in the feet (2 cases), a chronic sense of bursting fullness in the lower legs in patients who had varicose veins (3 cases) and various stations of psychoneurosis (8 cases). These are outside the scope of this paper.

GENERAL RESPONSES OF TISSUES TO

Before discussing the important subject, it will serve to orient one's concept, regard to review what is already known of the fundamental responses of the tissues to the pathologic changes that take place after severe chilling and immersion. On the literature, it is by the fact that there is no fundamental pathologic difference in the various responses to cold. There is a commonality to injuries due to both immersion and with Baron Larrey's⁵

snow of the trenches, particularly when unable to move about. Even then it was recognized that fatigue, stagnation of circulation, constriction of the legs and scurvy were important accessory factors. Greene,⁷ who as medical officer of two Himalayan expeditions had an unusually wide experience, has written a most timely account of the injuries that follow various forms of exposure to cold. He describes the trench-foot syndrome of the last war, which is essentially identical with that of immersion foot. Numbness gradually develops in cold, wet, dehydrated extremities, and is followed by swelling and blisters. When the blisters rupture, streptococci may bring about widespread gangrene, as well as in the prolonged exposure. It also is a descriptive term for the condition in lifeboats as the exposure is to break and pain in trench foot, which is in period of said shelters. The condition when the the bar of shiny and dry from vitamin

deficiency) are important accessory factors. Greene makes a brief reference to immersion foot, but states that he has never seen a case of it. The first comprehensive reports on this syndrome have been

is -1.9°C , it is obvious that, in immersion foot, actual freezing does not take place.

In investigating trench foot in the last war, Smith, Ritchie and Dawson¹⁰ carried out an ad

FIGURE 3 (1 of 2)

This seaman was in the same lifeboat as the man whose feet are shown in Figure 2. He also had no shoes, but his local injury from cold was much less pronounced. He was able to walk, and on admission to the hospital his feet were only slightly swollen, with hypesthesia of toes and intense hyperemia. Pain was severe, but after ten days' treatment in ice packs, circulation had returned to normal and the pain was no longer present so long as his feet were exposed to the cool air of the ward. The patches of gangrene shown in the photographs, taken on the twelfth day, were only skin deep.

published recently.^{1, 2} In addition, previous clinical and laboratory investigations are of value in understanding the underlying features of the condition.

The effects of cold with special reference to frostbite were studied by Rischpler⁷ in 1900. He froze animal tissues by the application of ice and salt, and investigated the results microscopically at various intervals. Under these circumstances actual degeneration was found in the cells of the blood vessel walls, with swelling of the connective tissue and vacuolation of the smooth muscle fibers, but there was no sign of thrombosis. During the last war, Luke⁸ found that the critical temperature where all metabolic processes are inhibited is -6°C (21°F). He claims that at this temperature blood freezes with destruction of cells liberating thrombokinase, and that on thawing thrombosis occurs. More recent studies by Lewis⁹ show that this is not necessarily true. Although the freezing point of blood is -0.53°C , and that of the tissues close to this level, Lewis found that skin when cold rarely freezes at its true freezing point. It exhibits the property of supercooling and may not freeze until the temperature falls to much lower levels, -20°C (-4°F). As the freezing point of sea water itself

is a mirable set of animal experiments under conditions that closely resemble those resulting in immersion foot. They subjected rabbits in a cold chamber to standing on wet mud. When this was continued for three days, especially after removing the fur from the paws, marked swelling of the feet resulted. Histologic examination showed changes in the blood vessel walls, with an outpouring of fluid containing both cells and fibrin. Occasionally the nerve trunks showed diffuse swelling of the axis cylinders, but without evidence of degenerating fibers in preparations stained by the Marchi method. The investigations thus proved that simple prolonged exposure to cold can produce subacute inflammation of the skin and subcutaneous tissues of the feet. These changes could be exaggerated by moisture, by applying constricting bands to the upper legs and by rapidly warming the chilled extremities before the animals were sacrificed.

The most illuminating discussion of the pathologic physiology of tissues exposed to cold is contained in a series of three lectures delivered by Sir Thomas Lewis¹¹ in 1941. On exposure to cold the blood vessels are constricted both by vasoconstrictor impulses from the hypothalamus and by direct contraction of the smooth muscle

TABLE 1. *Summary of Findings in Cases of Immersion-Foot Syndrome (Northern Survivors).*

CASE No.	TISSUE DAMAGE ON ARRIVAL AT HALIAX	FIRST SENSATION	PAIN		SENSORY LOSS	SWEATING	HYPEREMIA	TREATMENT	
			SEVERITY	DURATION				TYPE	DURATION
1	Swelling and blebs ++; gangrene of several toes.	Still absent	?	?	Distal half of feet	Absent below ankles	+++	Continuous ice packs Later, amputation of several toes	12 days

cells in their walls. But when the temperature of the skin drops near to freezing, there is an intermittent increase in blood flow, which serves to maintain the viability of the skin. This phenomenon is carried out by a special mechanism of arteriovenous anastomoses (Grant and Bland¹²) and is mediated by local axone reflexes. How long this mechanism can maintain its efficiency in the cold is not known, and it seems probable that the circulation must be reduced to a low point. Lewis observed that immersion of the normal hand or foot in water at 5°C. (41°F.) for as short a period as two hours resulted in definite swelling. This swelling, which may amount to as much as a 15 per cent increase in volume, is not the simple result of imbibition of water by the skin, since it happens in a hand protected by grease or covered by a rubber glove. If swelling of this degree can occur after a few hours, it is obvious that large amounts of fluid must be lost from the circulation on prolonged general exposure. The reduction in the circulating blood volume is the cause of the somnolence and death that overtake so many seamen in lifeboats during severe winter weather. Lewis considers this response to cold to be caused by an "H," histamine-like substance released from the injured cells and acting on the blood vessels.

When the chilled extremity is removed from ice water, the invariable response is a state of hyperemia. The local reddening, vasodilatation and extravasation of fluid from the injured vascular bed are all part of Lewis's classic "triple response." The wheal which first forms may be replaced by a blister. These changes together constitute a simple acute inflammation. Sections of human skin examined by Lewis twenty-four hours after chilling displayed edema of both epidermis and dermis, and a perivascular infiltration of the superficial layers of the dermis with lymphocytes, extravasated red blood cells and some polymorphonuclear leukocytes. Observations now completed in Halifax on many cases of immersion foot show that this inflammatory hyperemia reaches its height on about the third day after the period of exposure is ended and gradually disappears in the course of a fortnight, much as occurs in any other sterile inflammatory reaction.

The changes that occur in the nerve trunks and the terminal superficial axones to the skin are a second point of particular interest. These patients at first have complete cutaneous anesthesia below the ankles. In the mild cases this clears rapidly on warming, but in the severe ones there is still anesthesia of the toes at the end of a fortnight and reduced sensation over the remainder

of the foot. The speed at which sensory recovery may take place over the dorsum of the foot is too great for nerve regeneration and is evidence that the majority of nerve fibers never actually degenerate. This fits in with Smith, Ritchie and Dawson's¹⁰ observations in rabbits' feet after seventy-two hours' exposure to cold. They found definite swelling of the axones, but no evidence of their degeneration. However, in some of the patients of this series (Cases 1, 3 and 10) the toes were still anesthetic at the end of a fortnight and there was little sweating below the ankle. This suggests actual degeneration of the sensory and sympathetic axones to the more exposed distal portions of the feet, which may require a period of several months for complete regeneration and restoration of normal function. In Ungley's² recent report on the Scottish cases, Wallerian degeneration of some of the cutaneous nerves was observed by Blackwood, who examined the biopsies. It is a well-known fact that a partially injured nerve is likely to produce a painful neuritis, and this has been the universal experience in the severe cases of immersion foot. Accurate objective determinations of the recovery of nerves can be made by testing the return of sweating by the method recently described by Minor¹³ and by Guttman¹⁴ at Oxford, and the changes in electrical skin resistance (Richter and Woodruff¹⁵). These methods will be utilized when suitable patients are available in Boston.

The fact that patients continue to suffer after their circulation has returned to normal suggests that the pain is neuritic in origin. This is the most logical explanation in the late stages, but during the acute phase of the reaction this may not be the entire reason. In this connection it is of interest to quote the impression of Webster and his colleagues¹ that these men are comfortable when their foot temperature is kept below 80°F., but that as soon as the ice packs are left off and the cutaneous temperature of the toes is allowed to exceed 90°F. they again experience pain. This fits in with the observations made by Freeman¹⁶ on legs with threatened gangrene. By plethysmographic studies of blood flow in sympathetomized extremities, he has demonstrated that a rise with local heating is caused solely by the increased metabolism of the tissue cells and their need for more blood and oxygen. Local cellular metabolism, like other chemical reactions, should double or treble the consumption of oxygen for each 20°F. rise in tissue temperature. This chemical vasodilatation is not active at temperatures below 85°F., but increases rapidly at higher levels. As a result, if the supply of blood to the tissues is not correspondingly increased, the cells must suffer

oxygen want and this is invariably a cause of pain. Whereas the blood flow through the main pedal vessels is increased tremendously during the phase of acute hyperemia, there is good evidence that the cutaneous arterioles and capillaries have been injured and that therefore there may be a disparity between the supply and the demand for oxygen on the part of the tissue cells surrounding the cutaneous network of sensory nerve endings. On these physiologic grounds moderate cooling of the skin that is involved in a sterile inflammatory process will reduce the metabolic demand for oxygen. If demand can be made commensurate with supply, pain will be alleviated. Lewis¹⁷ stated that spontaneous pain occurs in skin rendered hyperalgesic by heat and other types of injury, and that it is enhanced by warming and relieved or abolished by cooling. Both these factors constitute strong arguments for therapeutic cooling of hyperemic painful feet during the early stage of the post-immersion reaction. Actual experience has borne this out, as it has been found that reducing the cutaneous temperature to 80°F. gives consistent relief in the acute stage.

From a consideration of the above facts concerning the reaction of the tissues to cold, it becomes evident that the common denominator in all conditions that follow thermal insults is injury to the blood vessels and nerves. As Lake⁸ pointed out, "a vicious circle is set up, for the greater the exudation the greater the venous obstruction, and the greater the venous obstruction the greater the rise in capillary pressure, and hence the greater the exudation."

TREATMENT

Prophylaxis

All ship's officers and seamen should be acquainted with the dangers of exposure to cold air and water. When there is sufficient time before abandoning ship, all hands should get into the most waterproof and loosely fitting boots they can obtain and take along extra pairs of heavy socks. If waterproof boots ship water and are wet inside, much can be accomplished by emptying them out periodically and putting on another pair of socks. This is the case even when the socks have been previously wet, provided they are wrung out and partially dried. Much can be done to prevent frostbite of the hands and feet by greasing the skin. Lewis⁹ pointed out that the property of "supercooling" is abolished by wetting and washing the skin, but is greatly enhanced by greasing. A further point to remember is that men in crowded lifeboats must remain fairly immobile, with their legs dependent. Movement of

the cold, benumbed extremities, even temporary elevation, and avoidance of constricting pressure on the legs from clothing or boat gear are helpful factors in preventing severe injury.

First-Aid

When shipwrecked survivors are picked up after prolonged exposure to wet and cold, they should be lifted aboard the rescuing vessel and carried below if their feet are numb, in order to prevent further injury to the anesthetic skin. The possibility of a severe reactive hyperemia and subsequent neuritic pain in the feet must be anticipated, even if actual gangrene from freezing has been avoided. These men require treatment for general as well as local chilling. Methods for dealing with the former are simple and well established, but while external and internal heat is being applied as a first-aid measure to the body as a whole, it should be borne in mind that the chilled extremities will suffer if they are warmed with equal rapidity. It is vitally important, therefore, to warm the patient as a whole first and prevent the chilled, bloodless extremity from increasing its metabolic demand for oxygen more rapidly than it can be supplied by a tardy restoration of the peripheral circulation. Although an appreciation of the risks of warming chilled extremities has been handed down as part of the folklore of the Eskimo, and the danger of this procedure was clearly understood by Larrey³ over a century ago, it is not generally recognized by seamen today.

Whether a person has suffered actual freezing or the less severe chilling seen in immersion foot may not be at first apparent, but in either case the immediate local treatment is the same. It should consist in keeping the exposed extremity cool, elevated slightly above the level of the heart and surgically clean. There is no previous medical experience to point out the most effective methods of attaining these ends, and whatever methods are proposed here will undoubtedly be modified and improved. As local first-aid treatment on shipboard I suggest the following:

1. Give the skin of the feet a preliminary cleansing with soap and cool water. This is to remove superficial dirt and bacteria, which may cause infection of the blisters and thus open the way to cellulitis and moist gangrene. Surgical cleanliness should be scrupulously maintained until the blebs are resorbed and the danger of infection is past. If the blisters have ruptured, do not apply any antiseptics. Dust these raw areas with sulfanilamide powder or cover with sulfathiazole ointment, but if neither is available leave

them alone. On transferring these patients to a hospital ashore, the feet can best be protected against bacterial contamination from blankets and handling by covering them with a sterile towel or bandage (if available), or clean cotton socks.

2. Keep the feet cool by exposure to the room air. Have no bedclothes below the knees, the room cooled below 70°F., and, if possible, direct cool air from a blower or electric fan over the exposed feet and legs.

3. Avoid pressure points on the feet, especially the heels, and elevate the feet on a pillow. Under no circumstances permit these patients to sit up with their legs dependent, as this increases swelling. Elevate the legs so that the feet will be above the level of the heart and thereby promote drainage of edema fluid. Remember that anesthetic, swollen feet are vulnerable to trauma and infection. For this reason even gentle rubbing or massage is dangerous.

4. Use codeine or morphine as necessary to control pain.

Hospital

On arrival in the hospital, the severe cases have pronounced swelling, blebs and discoloration. They have the greatest amount of anesthesia and, for the first few days, the least pain. Hyperemia is striking, with dilatation of the main arteries and prominent veins, but circulation through the cutaneous arterioles and capillaries is nevertheless inadequate, as shown by a dusky cyanotic color and minute hemorrhages in the skin. As explained above, the rationale of treatment at this stage is to reduce tissue metabolism to a point where there is an adequate supply of oxygen to all the cells. This can be accomplished by cooling the skin 5 to 10°F. — to a point below 85°*. Experience has already shown that, under these conditions, color improves, blebs tend to resorb, and edema is reduced.[†] In the mild cases this degree of cooling can be brought about by simple exposure to room air, provided the ward temperature is kept below 70°F. Slightly greater chilling can be obtained by having an electric fan on a bedtable blow air over the feet (Fig. 4), and this can be rendered more effective still if the patient occasionally sprays water from an atomizer into the stream of air from the fan.

Lake deserves the credit for being the first to suggest treatment by controlled cooling. In 1917 he wrote, "It would appear better to keep the limb cool by the application of wet cloths, until efficient treatment can be given, than to allow partial warming to occur." The Halifax experience has, however, demonstrated that wetting the skin is deleterious because it causes maceration.

†This is also true in an experimental burn. Drs. Oliver Cope and George Meier, Jr.,¹² have shown that cooling the burned leg of a dog to 50°F. reduces edema formation to a striking degree, with a corresponding reduction in vascular extravasation and lymph production.

During the most intense stage of hot, congested feet, and also when the neuritic pains are severest, neither of the above measures is effective. The naval medical officers in Halifax have worked out a very satisfactory type of ice pack for use under these circumstances. This consists of a cotton hand

FIGURE 4 Method of Cooling Feet by Exposure to Room Air Supplemented by Electric Fan.

Note that the legs are elevated and that the heels are protected from pressure by a pillow under the calves. The injection of a fine spray of water into the revolving fan blades with an atomizer further increases the cooling.

towel to cover the foot; four ice bags applied over the dorsum, soles and sides of the foot; oil-silk wrappings to 12 cm. above the malleoli; a thick insulating pad of fluffed cotton or cellulose; and a rubber pillowcase tied loosely about the calf of the leg. The purpose of this pack is not to induce severe chilling, which might lead to further trophic disturbances, but to cool the skin of the foot and toes to a level between 80 and 85°F. During the early, intensely hyperemic stage a thermocouple inserted next to the skin shows that the temperature of the foot does not fall below 90°F., although the toe temperatures may drop 5 to 10° farther. At this period the active circulation causes rapid melting of the ice. The packs should be changed at four-hour intervals and observations of skin temperature made at these times to control their application. In Case 2 the feet maintained this intense hyperemia in continuous ice packs for the first eleven days, but on the twelfth day of treatment they became distinctly cool. The ice packs were then discontinued and treatment by exposure to cool air begun.

From this point on the patient can usually be made comfortable by simple exposure of his legs from the knees down, supplemented if necessary by a breeze from an electric fan as mentioned above. At night, however, the neuritic pains may increase in intensity. The patients appreciate the

value of the ice packs for relieving pain and often request their reapplication. Under these circumstances a less elaborate pack is usually sufficient, consisting of a cotton towel to cover the foot, two ice bags on the dorsal and plantar surfaces and a large bath-towel wrapping.

In carrying out treatment with ice packs it is important to make sure that they do not leak and wet the skin. Each time this has occurred it has caused soggy and maceration.

In all the patients tested during the hyperemic stage, and even when it was subsiding, hanging the feet over the side of the bed caused striking congestion and pain. Conversely, elevation made the feet more comfortable. Many of the men discovered this for themselves and elevated their legs at the time of painful crises. The elevation need not exceed 20°. This is the best position for patients who are being treated by simple exposure of the legs to cool air, with or without an electric fan (Fig. 4).

On a theoretical basis, I advocate a period of Buerger's exercises prior to getting the patients out of bed. In these exercises, which are so useful in cases of threatened gangrene from arteriosclerosis or thromboangiitis obliterans, the feet are first hung over the side of the bed for four minutes, while the patient exercises the foot muscles by dorsiflexion and plantar flexion, inversion and eversion at the ankle and then flexion and extension of the toes. The feet are next elevated 45° for one minute, and then rested flat on the bed for five minutes. Cycles of these exercises carried out for half-hour periods three to four times a day should be tried as soon as the patient can tolerate the dependent position, and continued conscientiously for a week before permitting him to get out of bed.

Another measure often helpful in the early stage of edema and neuritic pain, particularly after prolonged exposure with starvation, is a diet high in protein and vitamin B. This is of specific value in survivors who have been adrift for long periods on a deficient diet, as will be shown in the second part of this paper.

On the basis of the similarity between the swelling due to immersion in cold water and that secondary to a burn, Koch's¹⁹ method of compression dressings might be a valuable adjunct in treating patients with particularly severe edema and bleb formation, provided hyperesthesia of the skin is not a major complication. I hope to have the opportunity to give it a trial this coming winter. However, in view of the fact that thermal injuries from cold often have associated cutaneous anesthesia, care will have to be used in applying a tight dressing, in order to avoid trophic ulceration.

Operations for Relief of Pain and Vasospasm

Smithwick and White²⁰ have advocated crushing the peripheral nerves through small incisions above the ankle for the relief of intractable pain in cases of peripheral vascular disease. This operation has been extensively employed during the past twelve years and has proved valuable. When the nerves regenerate, as they do regularly in three months, they do so without pain. Such a procedure should also be of value in the control of the neuritic pain of immersion foot, provided cases occur with such severity that the methods given above prove inadequate. To test this out I injected the posterior tibial and the superficial and deep peroneal nerves in Case 10 with a 2 per cent solution of procaine and found that the patient obtained complete relief for a period of two hours. Nerve crushing should be reserved for the severe cases, as it will incapacitate the subject for duty for three months, the period required for full regeneration of the nerves.

Blocking the sympathetic outflow to the lower extremities by therapeutic paravertebral injections of procaine hydrochloride and by lumbar sympathectomy has been suggested by a number of French and American surgeons, notably Leriche,²¹ Simon and Filhoulaud,²² Soupault and Orsini,²³ Forster and Wiederkehr²⁴ and Veal and Klepser.²⁵ I am unable to see how any possible improvement can result from such procedures during the acute stage. Absence of sweating proves that the terminal vasoconstrictor fibers are already interrupted, and the local hyperemia is more intense than that produced by sympathectomy. Indeed, the suggestions of Lewis and Love²⁶, and of Lake⁸ that steps should be taken to constrict the main arteries seem more rational. As Greene⁵ has stated, "it is to be hoped that without careful previous animal experiments no surgeons will be tempted to follow in the footsteps of these French colleagues." To see if the pain of immersion foot could be relieved by interruption of the sympathetic vasoconstrictors, I blocked the lumbar ganglia with procaine in Case 10. The patient's pain was not influenced in any way, but as I am not convinced that the sympathetic pathways were entirely interrupted, the test should be repeated. On the other hand, procaine injection of the posterior tibial and the superficial and deep peroneal nerves above the angle in the same patient abolished the pain completely.

The only case where lumbar sympathectomy is likely to be of value is in the late stages when the circulation of the foot remains insufficient. Four of the Halifax patients after recovery had unusual

ly cold and sweaty hands as well as feet—a mild variety of Raynaud's disease. One of these (Case 19) who had had a Syme's amputation, continued to be incapacitated by ulceration at the end of the stump. He was tested by procaine block of the vasoconstrictor fibers (both by lumbar paravertebral and by subarachnoid spinal block), but showed no appreciable rise in cutaneous temperature in the ulcerated area. This was evidently due to organic narrowing of the peripheral vessels, secondary to his unusually prolonged chilling and septic gangrene. Nevertheless, cases will undoubtedly occur, as has already been observed in frostbite, where an inadequate circulation in the late stages of severe immersion foot (with secondary arterial occlusion) can be benefited by lumbar sympathetic ganglionectomy. A number of such patients, who six months after their initial exposure are still suffering from cold and pain in their feet, are under investigation at the United States Naval Hospital in Chelsea at the present moment. In addition to the inadequate circulation of their feet, the presence of increased sweating and of vasomotor changes in their hands indicates that they have an underlying vasomotor syndrome. Although it is unlikely that this condition originated with the exposure, it was probably increased by the psychic trauma.²⁷ Permanent vasodilatation may well result in secondary relief of the deep plantar pain.

PROGNOSIS

Although it is too early to give accurate statistics of the end-results in immersion foot, it appears that the majority of patients respond favorably to the methods of treatment described above and should be able to return to duty within a month or six weeks. In the rare cases where gangrene develops or there is pre-existent peripheral vascular disease, and particularly when the sufferer has the misfortune to develop a psychoneurosis, convalescence may be very protracted.

SUMMARY AND CONCLUSIONS

Immersion foot, secondary to exposure to cold, appears to be caused by sublethal injury to the chilled tissue cells, the cutaneous arteriolar and capillary bed and the nerve fibers. The process differs only in the degree of chilling and wetting from frostbite, trench foot and shelter foot.

The ischemia during prolonged exposure to intense cold is followed by a period of acute inflammation. The hyperemic reaction of the feet is due mainly to the chemical effects of the products of tissue injury. Paralysis of the vasoconstrictor fibers is an added factor, but is of secondary importance.

In spite of the increased flow of blood in the main vessels, there is a disparity between the blood-oxygen supply and demand in the cutaneous capillary bed. Capillary permeability is thereby increased. Edema, pain and petechial hemorrhages, as well as the congestion seen when the feet are in the dependent position, are evidence of injury to the blood vessels. By cooling and reducing the local metabolism and need for oxygen, both edema and pain are diminished.

The inflammatory reaction and hyperemia fade in a few weeks, and the circulation usually returns to normal at this time.

Neuritic pain makes its appearance with partial recovery of the nerves and continues until nerve function is restored. It has disappeared within two weeks in some of the mild cases seen in Halifax, but it is impossible as yet to tell how long it may last in the severe ones. In some of the survivors observed in Scotland and in this series, it was troublesome for nearly six months.

Much can be accomplished by suitable treatment. This must be directed primarily at reducing local tissue metabolism in the early period and in preventing further injury and infection of the insensitive swollen feet. Gangrene should be a rare complication.

The rationale and methods of treatment developed so far are outlined, with suggestions for future investigation.

Not all cases of swollen painful feet seen in shipwrecked survivors are due to immersion in cold water. Cases in which this condition has developed in a tropical climate will be discussed in the second part of this paper.

FIEDLER'S MYOCARDITIS*

Report of a Case

H. T. ENGELHARDT, M.D.,† AND F. E. BRUNO, M.D.‡

NEW ORLEANS, LOUISIANA

SINCE Fiedler¹ first described interstitial myocarditis in 1900, there have been to our knowledge 9 reported cases of this entity in the American literature. Attention was first directed to this unusual form of myocarditis in the United States by Scott and Saphir.² In the world literature we were able to find at least 46 cases that conform to the pathologic criteria consistent with this syndrome.

Many quasi-descriptive terms have been used to identify the condition. Acute interstitial myocarditis was proposed by Fiedler. Later other synonyms were applied, and terms such as acute isolated interstitial myocarditis³; acute, subacute and chronic isolated myocarditis^{4,5}; myocarditis perniciosa⁶ and granulomatous myocarditis⁷ have appeared in reviews and case reports of this condition.

Because of the rarity of this syndrome, we believe that a brief survey of the literature and the report of an additional case are justified.

CASE REPORT

L. E., a 29-year-old housewife, was admitted to the Tulane Medical Service on October 21, 1939. She had been perfectly well until August of that year, when she experienced a sudden attack of "smothering" while doing her daily housework. At this time she was conscious of her heart's palpitating and was unable to get her breath. In a few minutes she was able to resume her work. Following this attack, she had occasional periods of dyspnea on exertion, which became progressively greater. Nine weeks prior to admission she began to experience attacks of paroxysmal nocturnal dyspnea. At about this time she began to require two to three pillows at night and

developed a cough productive of frothy sputum. Her activity was greatly restricted. Despite this the attacks of dyspnea became more frequent. On October 11, 1939, the patient was ordered to bed by her physician. At about this time she began to develop upper abdominal pain, noticed swelling of the upper abdomen, and began to vomit bile-stained material. Because of her failure to improve, the patient was referred to the Charity Hospital.

The past history was relevant in so far as it showed that the patient had had a cholecystectomy for cholecystitis and cholelithiasis 3 years previously. She had had "kidney trouble" and "high blood pressure" with a pregnancy 7 years previously. Subsequent follow-up over a period of years revealed no hypertension.

Physical examination disclosed an obese white woman who appeared to be of her stated age. The temperature was 100.4°F., the blood pressure 120/80, the respirations 30 and somewhat labored, and the pulse 108. There was enlargement of the right lobe of the thyroid gland, which was firm and smooth. Examination of the chest revealed lagging on the right side. The point of maximal cardiac impulse was felt in the 6th left interspace 8 cm. from the midsternal line. Tactile fremitus was diminished on the right posteriorly. There was dullness to percussion in this area below the 4th interspace. There was no enlargement of the heart to the right. The left border of cardiac dullness was 9 cm. from the sternal line in the 6th interspace. Breath sounds were heard with difficulty at the bases of the lungs, and vocal fremitus was greater on the left than on the right. Auscultation of the heart revealed no murmurs. The remainder of the physical examination was not noteworthy.

The red-cell count was 5,250,000, the hemoglobin 70 per cent, and the white-cell blood count 15,000, with a normal differential. The sedimentation rate was 20 mm. in 1 hour. Urinalysis was not significant, the specific gravity being reported as 1.022. The blood Wassermann reaction was negative. A roentgenogram of the chest was reported as showing enlargement of the cardiac shadow with evidence of pulmonary congestion. There was evidence of some fluid in the right pleural cavity.

The patient was digitalized, given oxygen by nasal catheter, and a thoracentesis of the right chest on October 22 yielded 1000 cc. of straw-colored fluid. Two days

‡Formerly, assistant in medicine, Tulane University of Louisiana School of Medicine, and assistant visiting physician, Charity Hospital.

after admission a gallop rhythm and frequent ectopic beats were heard. A few days later the temperature rose to 100.2°F, and the patient ran an irregular fever for 9 days, *no cause other than pulmonary congestion being found.*

The basal metabolism was as follows: on November 8 the rate was +23 per cent, on November 10, +13 per cent, and on November 15, +3 per cent. Electrocardiogram made on October 23 revealed occasional ventricular premature beats and low, bizarre QRS complexes. T_2 was diphasic, and there was depression of the RST segment in Leads I and 2. The interpretation of the electrocardiographic evidence was extensive myocardial disease.

On November 25 the patient left the hospital against advice.

After leaving the hospital the patient felt quite well until June, 1940, when she began to decompensate. In the interval between June and November she was admitted to the hospital on two occasions. Her fourth admission occurred on November 25, 1940, when she returned at the request of the staff for further observation. At that time the blood pressure was 110/68. Investigation revealed that the heart had undergone progressive enlargement, particularly to the left. This was confirmed by roentgenologic examination.

On August 12, 1941, the patient was readmitted for the fifth time. She had been taking digitalis regularly up to 1 month before admission, when, on the advice of her physician, it was stopped for 14 days. In 2 weeks she developed dyspnea, palpitation and edema. Digitalis was resumed, but because of her heart failure she was advised to return to the hospital.

At the time of this readmission the temperature was 99°F, the pulse 90, and the blood pressure 130/80. Congestive rales could be heard at both bases up to the mid-lung fields. The heart border was percussed 4 cm. to the right of the sternal line and 13 cm. to the left of the midline in the 6th interspace. A gallop rhythm was heard. There were frequent ectopic beats and at times bigeminy was thought to be present. A pulse alternation of 10 mm. of mercury was noted. A systolic mitral murmur was heard. The liver was palpable three finger-breadths below the costal margin. Moderate edema of the feet, legs, sacrum and hips was present. The venous pressure was 24.8 cm., and the Decholin circulation time was 45 seconds. The patient was redigitalized and slowly improved, and early in September was allowed out of bed for short intervals. On September 21, she began to feel nauseated, vomited, and complained of abdominal pain. Because she was theoretically digitalized or perhaps overdigitalized, the drug was discontinued. She rapidly became worse, complained of dyspnea, and digitalis was resumed on September 24, with little effect. On September 28 the patient became extremely dyspneic and oxygen was ordered. She expired at 3:30 p.m. on September 29.

Autopsy. The outstanding pathologic changes were present in the heart, which weighed 450 gm. The epicardium was smooth and shiny, and the myocardium was relatively flabby. The coronaries were widely patent. In the region of the apex in the left ventricle there was a brownish, softened area that shrank beneath the cut surface and measured 0.8 cm. in diameter. In the inferior region of the left ventricle there was a firm, whitened scar penetrating a columna carnea that was approximately 1 cm. in length. The mitral valve had a number of wart-like protuberances, which appeared to be of the arteriosclerotic type. They were much larger than rheumatic lesions, being approximately 0.4 cm. in diameter. The

auricular endocardium above the mitral valve was thrown into threadlike folds and projections. Measurements were as follows: tricuspid valve, 130 cm; pulmonary valve, 74 cm; mitral valve, 107 cm; aortic valve, 60 cm; right ventricle, 05 cm, and left ventricle, 1.6 cm. The

FIGURE 1.

columnae carnea of the left ventricle were filled with grayish, apparently organized but easily removable thrombi. The other findings were pulmonary edema and congestion, chronic passive congestion of the liver and spleen and follicular cysts of the ovary. The thyroid gland showed no evidence of disease.

Microscopic examination of the heart revealed many areas of inflammation in the myocardium, varying in de-

FIGURE 2.

gree and character. There was evidence of injury and repair of the muscle fibers associated with an infiltration consisting chiefly of lymphoid cells and an occasional polymorphonuclear leukocyte and phagocytic cell. Small areas of interstitial hemorrhage were present, but these were not remarkably prominent. There were areas where the degree of hydrops of the muscle was extreme (Fig. 1). At other sites an older lesion was demonstrable in which fibroblastic proliferation dominated the picture (Fig. 2).

DISCUSSION

The history and personal observations of the course of this case lead us to conclude that the disease began in June, 1939, and progressed to the patient's death in September, 1941. Search of the available literature on this subject discloses no other case of a patient with Fiedler's myocarditis surviving more than twenty-one months.

Many authors have attempted to incriminate definite etiologic factors that have been observed in connection with this disease. In the individual case reports carbuncles, gonorrheal urethritis, upper-respiratory infection, influenza, "rheumatism," syphilis and status thymicolymphaticus have been described as being associated in patients who have been found at necropsy to have interstitial myocarditis. Such an association is believed by most authorities to be coincidental and as yet no definite etiologic relations have been established.

Clinically no constant progression of symptoms and signs that is diagnostic of this pathologic entity is known. Its manifestations are protean. The reported cases show no preponderance of either sex. The disease occurs primarily between the ages of eighteen and fifty, although cases have been observed in patients as young as nineteen months^{8,9} and as old as sixty-nine years. The onset in the majority of cases is abrupt and may be accompanied by a chill. It may, however, be initiated by upper respiratory symptoms, such as cough, dyspnea, hemoptysis, generalized weakness and precordial distress.

Physical examination usually reveals no findings of any consequence. Some cases have presented evidences of focal infection of varying severity. There has been in some cases a slight but definite elevation of temperature for which no explanation was evident. In general the heart is enlarged, predominantly to the left, and at times a soft apical systolic murmur is heard. The rate is invariably accelerated, and a gallop rhythm has been described. There have been comparatively few electrocardiographic studies, but most of those reported presented evidence of definite myocardial damage. Despite this no diagnostic electrocardiographic criteria have been established for the condition.

The duration of the disease has been found to range from two days¹⁰ to twenty-one months.⁵ In

fact, one case is reported¹⁰ in which a patient died suddenly from a rupture of the left ventricle four days after a convulsive seizure. In the usual case, however, the disease will have run its course after a few months.

The histopathologic picture of this entity is characterized by typical findings.¹¹ There is usually an interstitial infiltration of the myocardium, which is chiefly due to lymphocytes, monocytes and, to a certain extent, neutrophils, eosinophils and plasma cells. Areas of necrosis are not infrequently found in the muscle fibers. This injury is diffuse throughout the myocardium. In some cases, hemorrhages have been described, due in all probability to the rupture of hyalinized muscle fibers. In the more chronic cases these areas are replaced by acellular fibrous scars. There may be actual granulation tissue with new capillary formation and fibroblastic proliferation.

Covey¹² emphasizes that no descriptions or illustrations contain all the abnormalities of the aggregate but that the variations pictured in the different case reports are insignificant when the whole is analyzed. It appears that whatever the etiologic agent may be, there is nothing in the histologic picture suggestive of a specific granuloma.

SUMMARY

A case of Fiedler's myocarditis is reported, and the significant clinical and pathological findings, as reported in the literature, are discussed.

MEDICAL PROGRESS

RESPIRATORY FAILURE IN ACUTE POLIOMYELITIS

CONRAD WESSELHOEFT, M.D.*

BOSTON

THE increased interest in the treatment of acute poliomyelitis awakened by the Kenny technic has resulted in a certain amount of confusion regarding the value of the respirator in the presence of respiratory failure in this disease. The Kenny school of thought has gone so far in its condemnation of "orthodox practices" in this disease as to advocate the abandonment of the respirator in favor of the application of hot packs to respiratory muscles. This willingness to scrap the respirators along with the immobilizing splints calls for a review of the many complex factors involved in respiratory failure in acute poliomyelitis.

The muscles of respiration consist of two groups, one of which is engaged in quiet breathing known as eupnea; the other group, composed of the accessory muscles of respiration, comes into play during labored breathing or dyspnea. In the first group, there is a variation in the part played by the different muscles according to whether the subject uses the abdominal or costal type of respiration. In the dyspnea met with in the spinal type of poliomyelitis, the exaggeration of the breathing effort is manifested in those muscles that are attempting to compensate for muscles either weakened or completely thrown out of commission by spasm or paralysis. A muscle or a group of muscles that is in spasm may not be completely lost so far as potential function is concerned. In fact, muscles with an uninjured nerve supply may be thrown into continued contraction by the spasm of opposing muscles,¹ the so-called "brake" phenomenon in Kenny terminology.² Thus it is that the number of respiratory muscles thrown out of commission may be out of all proportion to the actual number of muscles or muscle fibers directly affected by nerve damage. This lost function is compensated for by the increased effort of the remaining, freely active muscles. This effort varies not only according to the amount of function lost but also according to which muscles are affected. There may be exaggerated abdominal breathing to compensate for loss of

function in the thoracic group, or exaggerated thoracic breathing to compensate for loss of function in the abdominal group. But as the demand for compensation increases, the accessory muscles of respiration come more and more into activity in an effort to lengthen and expand, as well as to contract, the thorax.

ANATOMY

The muscles engaged in forced inspiration are numerous. First of all is the diaphragm, which on contraction pulls air into the chest and simultaneously pushes out the abdominal wall. The thorax is also elongated by the upward pull of the three pairs of scaleni on the first and second ribs. The sternocleidomastoid and trapezius serve as accessories in this accordion process. Expansion of the thorax is accomplished by contraction of the levatores costarum, the external intercostals and the serratus posticus superior. By their action the ribs are raised and the shafts slightly rotated outward. In addition to all these we have the accessory action of the rhomboidei, pectoralis major and minor, serratus magnus, latissimus dorsi and, finally, the extensors of the spine.

Forced expiration is accomplished by contraction of the abdominal muscles, which, with the glottis open, forces the dome of the diaphragm upward and outward. Engaged in this process of shortening the thoracic cavity are the external oblique, internal oblique, transversalis and rectus, whereas the internal intercostals, triangulæ sterni, transversus thoracis and serratus posticus inferior tend to contract the thorax.

Although the function of some of these muscles is open to debate, they nevertheless all come into play in dyspnea. It is worthy of note that some one hundred and twenty separate muscles, as enumerated above, may go into vigorous action in forced respiration. Furthermore, it is clear that many of these, including the diaphragm, are far removed from any direct influence of hot packs. However, one can imagine that if the external intercostals were thrown into spasm and if the internal intercostals were to go into spasm by reflex action, both sets might be benefited by the application of hot packs to the chest wall. In this connection, it is a matter of clinical experience

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress, Annual, Vol. III, 1942* (Springfield, Illinois: Charles C. Thomas Company, 1942, \$5.00).

*Clinical professor of communicable diseases, Harvard Medical School, chief, Haynes Memorial Hospital, Massachusetts Memorial Hospitals.

in poliomyelitis that the muscles of expiration show signs of serious fatigue sooner than do the muscles of inspiration. This coincides with the fact that even normal inspiration requires more muscular work than does expiration. The Drinker and the Emerson respirators, by creating rhythmic negative pressure, take over the work of the inspiratory muscles. The pulsator of Bragg and Paul, on the other hand, rhythmically compresses the chest wall by pressure from a rubber bag fastened about the chest. This compression takes the place of the expiratory muscles in forced expiration, as in the Schaefer method of resuscitation. Of the two, the respirator much more closely imitates normal respiration.

PHYSIOLOGY

The respiratory center in the medulla or bulb lies under the floor of the fourth ventricle in the region where the cranial nerves originate. This center has a right and a left half, which communicate with one another through the intrabulbar commissural fibers, giving a symmetry of respiratory movements. The main function of this center is to regulate the rhythm and the depth of the involuntary respiratory movements. It does this through afferent impulses arising from various sources which convey the body needs. From here also fibers pass directly downward without decussation to the respiratory motor nuclei in the anterior horns of the cord. Any impairment of this respiratory center in the medulla results in variations in rhythm and depth, and its destruction results in immediate cessation of respiration.

This respiratory center is in anatomic and physiologic relation to certain cranial nerves whose afferent fibers bring controlling impulses of inspiration and expiration. The most important of these is the vagus, the sensory fibers of which come from the lungs, bronchi, trachea and larynx, whereas the motor fibers supply these same areas, together with the pharynx and soft palate. These impulses exert essential influences for both the rate and the rhythm of involuntary respiration, and also for the more violent voluntary efforts of coughing.

Sensory fibers of the trigeminal nerve arising from the nasal mucous membrane have an important protective function. Any violent irritation of these nerve terminals by injurious gases inhibits breathing. The same effect is obtained from any marked irritation of the glossopharyngeal nerve. In fact, the sensory fibers of this nerve inhibit respiration whenever one swallows.

Involuntary respiration is under the control of the respiratory center in the bulb. Voluntary control comes from the cerebrum, as in talking, singing, whistling and any blowing effort. But there

are impulses that involuntarily interrupt the normal rhythm, such as yawning, laughing, sighing, crying and sobbing. Coughing and sneezing arise from irritation along the tract. Hiccup, a spasm of the diaphragm with closure of the glottis in the form of an extra inspiratory wave, can be induced by a wide variety of causes including irritation of the diaphragm, intoxication, encephalitis, irritation in the trapezius³ and exsanguination in its terminal stage. Of these all but the last may occur in poliomyelitis. The hiccup in this disease is a subject that in itself deserves extensive discussion.

SPINAL RESPIRATORY FAILURE

When a healthy individual is placed in a respirator, his respiratory rhythm is promptly taken over by the machine without his becoming aware of it until he tries to talk. He can articulate only with each expiration. He finds himself merely making motions of the tongue and lips during inspiration, and he cannot prolong expiration against the machine. A patient in the respirator learns very promptly—within a few minutes—how to talk and how to swallow nourishment, if minute amounts are given at first. He does not have to be taught by anyone: it is a matter of extraordinarily prompt adaptation to an artificial respiration that closely simulates normal breathing.

The respiratory center serves as the pacemaker for a wave of musculature contraction starting in the diaphragm and co-ordinately bringing into play those muscles of the thorax and abdomen that are needed. The diaphragm may "flutter" in post-encephalitic conditions and, in so doing, may carry the thoracic muscles along at the rate of 90 or even 200 contractions a minute, a very uneconomical form of respiration, with movement of air largely confined to the "dead spaces," and with very little change of air in the lung itself. Dowman⁴ and Skillern⁵ have shown that under these conditions, when the diaphragm is put out of commission by a double phrenectomy, the other respiratory muscles promptly return to a contraction rate of 20 per minute. Gamble, Pepper and Muller⁶ observed that occasionally in flutter the chest muscles would "miss" and, further, that immediately after prolonged holding of the breath or during sleep the diaphragmatic flutter would at times fall into an exact two-to-one rhythm with the thoracic excursions.

All this puts one in mind of the relation of the auricles to the ventricles in cardiac rhythm, an analogy discussed by Wenckebach.⁷ But there is a wide difference between the respiratory and the cardiac systems, since there is no pacemaker in the diaphragm and no "conduction system" other than the nerve supply from the respiratory center to the

respiratory muscles with the synapses in the spinal cord. Nevertheless, the co-ordination in the wave of contractions and the disturbances in rhythm offer an interesting comparison from a clinical viewpoint. An appreciation of these outward similarities helps one to recognize some of the respiratory phenomena observed in poliomyelitis.

In spinal poliomyelitis only one side of the diaphragm may be thrown out of commission.⁸ One may observe a patient getting along fairly satisfactorily with apparently a complete unilateral absence of contractions. Likewise a patient will sometimes appear to be getting along well with only the diaphragm and very little use of either the thoracic or the abdominal muscles. However, these patients should always be in close proximity to a respirator, and be put in at the first sign of fatigue. Although a patient may seem to be getting enough air under these conditions, he will often get relaxation and comfort in the respirator so that he promptly falls asleep.

Indications of impending failure in the spinal type of poliomyelitis consist of visible loss of action in the muscles of normal inspiration, with overaction of the sternocleidomastoid ("neck breathing") and other accessory muscles. The breathing is at first shallow and later labored. Speech is interrupted by inspirations so that the patient can count only to two or three before breathing in. Coughing becomes ineffective and then impossible. Cyanosis implies anoxemia, with lowered resistance to the infection as a whole, as well as loss of muscle strength. When all inspiratory effort is apparently on the point of exhaustion and the expiratory muscles appear to be attempting to compensate with a low vital capacity of air in the lungs, the need of a respirator is imperative. The ideal time to put the patient in is at the first signs of failure. Delay is to his distinct disadvantage.

The supportive value of the respirator when early fatigue is threatened is difficult to determine in statistics, yet it may be quite obvious to the patient and to the attending clinician. Nor does such a statement preclude the use of hot packs as an intermediate measure. Indeed, I have seen hot packs enhance the inspiratory effort of the thoracic muscles when these were lagging, but such benefit was temporary. One may assume that muscular spasm is relaxed by the heat, but certainly the heat does not reach a diaphragm in spasm. Whether the respirator has a salutary or detrimental influence on any of the respiratory muscles in spasm is unknown. At least, one can say that there is no danger of muscle-stretching. Short of complete paralysis there is certainly no rest for these muscles, in the true sense of the term, while life goes on. The respirator may secure rest to some of the over-

worked accessory muscles, but primarily it serves as a support to the muscles of normal quiet inspiration.

As pointed out by Wilson,⁹ the nearest approach to achieving rest for the respiratory muscles comes from the proper use of a respirator. This machine is to failure of the respiratory muscles what intubation is to laryngeal obstruction. In this comparison the preliminary trial of hot packs may be compared to the use of steam inhalations in laryngeal spasm. There are definite indications for the respirator as there are for intubation. Delay in the use of the respirator as with the tube results in fatigue and anoxemia, and may mean the difference between death and recovery. Just as the tube should not remain in any longer than is necessary, so also the patient should be weaned from the respirator as soon as possible. Ability to cough is a good indication for removal.¹⁰ The respiratory muscles can be "alienated" from the control of the respiratory center as definitely as the leg muscles can be "alienated" from the cortex by prolonged immobilization in a splint.

In complete and irreversible paralysis of the respiratory muscles, life can be maintained only by the continued use of the respirator. However, as pointed out by Wilson,¹¹ there is no way of telling at the beginning of muscular failure how much nerve damage is actually taking place. Nor, as he says, is there any room for philosophical discussion of one's duty as a physician even if one could foresee indefinite dependence on the respirator. Furthermore, the established fact that there is a high death rate from respiratory infections following the use of the respirator is also no argument against its use, since this also holds true after intubation and tracheotomy. Indeed, the utmost care should be used in respirator cases to avoid exposure to respiratory infections. All attendants should wear masks, and no visitor with a cold or sore throat should ever be allowed in the room.

The rate of the machine is not so important as the height of negative pressure. In the pure spinal type the patient's respiratory rate depends on the degree of failure, but once in the apparatus he promptly adapts himself to its rate. This is particularly shown in the room respirator where several patients are being treated at the same time.¹² The rate for children is usually between 20 and 30 per minute, and for adults between 15 and 20 per minute. The pressure, however, is a very different thing. The real danger of the machine lies here. Too great a negative pressure injures the alveoli of the lungs and thereby induces pneumonia.¹⁰ Children under ten years of age should be started at a pressure of 10-cm. on the water manometer, and this should never be to

rise above 14. Adults can be started at a pressure of 12 to 14 cm., and there is rarely any reason for allowing it to rise above 16, and never above 20. The four most important points to keep in mind in the use of the respirator in the spinal type of failure are these: avoid delay; wean as early as possible; avoid dangerously high negative pressure; prevent bedsores. The nursing care of respirator cases is described in a brochure put out by the National Foundation for Infantile Paralysis.¹³

BULBAR RESPIRATORY FAILURE

Respiratory paralysis in poliomyelitis is not confined to impairment of the respiratory muscles through injury to their spinal-nerve supply. The virus may attack other portions of the nervous system whereby respiration is affected, either directly at the respiratory center itself, or indirectly through injury to those cranial nerves supplying certain muscles that clear the respiratory tract by swallowing.

When the respiratory center itself becomes impaired, the respiration becomes irregular and jerky. This irregularity is not overcome by the respirator. In other words, the respiratory movements fail to synchronize with the machine. Along with this there may be long sighs or violent hiccups that add to the confusion of the breathing. In a way this may be compared to the twitching and fibrillation seen in the trapezius muscle when its anterior-horn cells are being invaded by the virus. Suddenly and without further warning respiration stops. On the other hand, one may see a marked slowing of the rate with deep inspirations, signifying pressure on the floor of the fourth ventricle from increased spinal-fluid pressure. Lumbar drainage promptly performed can offset such a situation, and with repetitions as needed may lead to the return of normal respirations as the pressure subsides.¹⁴

The function of deglutition is vital to respiration, as this keeps the upper respiratory tract clear. Any impairment of this function through injury to the cranial nerves supplying this area results in choking and finally drowning in mucus. This is the so-called "wet type" of respiratory failure. To speak of these patients as dying of pneumonia is misleading. Of course, they may do so later from a secondary infection. In these cases with inability to swallow the respirations are shallow and often irregular, because the patient hesitates to breathe for fear of inspirating mucus into the trachea.¹⁵ With laryngeal paralysis coughing becomes impaired because of an inability to close the glottis. Thus it becomes impossible to clear the throat by either swallowing or coughing. The accumulation of mucus tickles the underlying

mucous membrane, with the result that the secretion of mucus is rapidly augmented. Nausea may be an additional factor in the promotion of excessive mucus. It is possible that the invasion of the pharynx by the virus of poliomyelitis in these cases may also be another factor in this profuse secretion of mucus. The recent work of Sabin¹⁶ indicates that bulbar invasion originates from extension of the virus along the neurons supplying the pharynx, whereas spinal involvement originates from extension of the virus along the neurons supplying the intestine.

Landon and Smith,¹⁷ Kelleher¹⁸ and Emil Smith¹⁹ state that atropine is useful in drying up these secretions. Crone¹⁹ remarks that atropine gives only temporary and partial relief. Wilson²⁰ has found it unsatisfactory and believes that it may render the mucus more tenacious, more annoying to the patient and more difficult to remove. My own experience is that, although atropine is oftener useless than helpful, it has at times appeared to slow up the secretions perceptibly.

Suction applied to the pharynx is a great help, but it must be exerted very gently. Anderson²¹ uses a rubber catheter with numerous openings near the tip. This is passed through one nostril down into the pharynx and constant suction is applied. With sufficient skill a tube may be passed through the other nostril and down through the esophagus to the stomach for the purpose of feeding. Needless to say, one must be sure that this tube lies in the stomach. The foot of the bed is raised sufficiently to give the trachea enough of a downward slant to procure gravity drainage.

Postural drainage is of far greater importance than either atropine or suction, as has been graphically brought out by the cases reported by Durand.²² With the foot of the bed raised 2 feet enormous quantities of this mucus—a pint or more—will run from the nose and mouth in spite of the administration of atropine. The patient's position can be shifted from one side to the other—better still with the face down but turned to the side.

The respirator is not only useless for correcting the embarrassment to respiration in bulbar poliomyelitis, but can be actually harmful. As has already been said, when the respiratory center is involved the patient's breathing does not synchronize with the machine. Thus the machine interferes with his breathing instead of supporting it, and he begs to be taken out. When cranial-nerve involvement causes pharyngeal paralysis, the respirator causes the mucus to be forcibly drawn down into the trachea, whereas the patient's own intuition prompts him to avoid this by shallow breathing. Nevertheless, it must be clearly

understood that a patient may have a combination of spinal and bulbar involvement, and the spinal involvement may be sufficiently severe to warrant a trial of the respirator, provided precautions are taken against the effects of the bulbar paralysis. Especially is this true where the spinal involvement is severe and the bulbar involvement is mild. When pharyngeal paralysis is combined with the spinal type, an inlaid catheter with constant suction can be tried along with the respirator. To meet this combination of circumstances a respirator is now available that can be adjusted like an operating table and thus afford postural drainage as well. However, the mortality rate in these cases is always high, especially in those with the ascending type of paralysis.

* * *

There is one condition that occurs, especially in the ascending type of spinal paralysis, where the respirator becomes useless. The abdominal muscles become paralyzed first, as their nerve supply comes from the dorsal segments of the cord. Next, the thoracic muscles cease to function, their nerve supply coming from the cervical segments. If the diaphragm, which is also supplied by the cervical segments, holds out long enough to get the patient to a respirator, dramatic and immediate relief may be obtained. But unfortunately, the paralysis of the intestinal tract then begins to manifest itself with absolute stasis and increasing abdominal distention. Hot stupes, enemas and the rectal tube become ineffectual. A Miller-Abbott tube cannot be worked down beyond the pylorus under these conditions. The weakened and eventually paralyzed diaphragm is forced higher and higher. Finally the negative pressure of the respirator, even when increased to 30 cm. on the water manometer, fails to enlarge this contracted thoracic cage. A respiratory standstill may thus ensue in spite of the respirator before the medulla is encroached on.

Condemnation of the respirator by the close adherents of the Kenny method has been uttered from the lecture platform. I witnessed this in the crowded Kenny booth at the last meeting of the American Medical Association in Atlantic City, and again at the course given at the University of Minnesota last July, where the lecture and motion picture dealing with respiratory paralysis were unforgivably narrow in scope and in tone. This exercise was not conducted by Sister Kenny. In her book Sister Kenny² describes the success of her treatment in two early "respirator cases" in which the patients were "unable to swallow," and in a spinal case where artificial respiration by "gently depressing the floating ribs" was

resorted to five days after the onset of the poliomyelitis. She describes it as a form of "muscle education"—that is, teaching the patient to breathe. That Sister Kenny inspires confidence in her patients and overcomes their fears is one of her great assets. But one is also impressed by her outspoken prejudice against all orthodox treatment. Thus, she prefers the old method of resuscitation that all physicians had to use before the invention of the respirator. A careful analysis of the respiratory cases treated by Daly and her associates²³ by the Kenny method is not at all impressive in this particular respect, although otherwise it is highly instructive. Enthusiasm for the Kenny technic has led many to accept it as an all-embracing system of treatment for poliomyelitis. Such an attitude is out of keeping with the professed philosophy of Sister Kenny herself at her highest moments as a teacher. Hot packs to the chest, neck and abdomen may be advantageously applied in the earliest stage prior to insertion in the respirator and on removal from it, or where no respirator is available.

The use of the respirator is fraught with many discouraging experiences. Some are due to the types and complications of the respiratory failure, but others result from the overwhelming damage brought about by the progress of the disease. These experiences have been stressed by all authors, and powerfully expressed in an editorial.²⁴ Nevertheless, on the credit side there are an ample number of patients who have obtained comfort, relaxation and sleep at a critical period of respiratory embarrassment, and who later have walked out of the hospital to lead useful lives. It is impossible to draw up an adequate protocol of the results of respirator treatment over the last decade, because of the relatively small number of publications on this subject. However, in a survey of the year 1940 Wilson²⁴ found that among 127 cases with simple intercostal or diaphragmatic paralysis treated in the respirator, 81 per cent survived. The survey could not include the end-results regarding permanent handicaps. It did bring out that in general the respirator was too frequently used where it was not indicated, and that where indicated its use had too often been delayed to the distinct disadvantage of the patient. Unqualified disparaging statements regarding the value of the respirator increase these delays. The Kenny method has much in its favor, but as yet no figures have been produced to show that hot packs can replace the position now held by the respirator in the treatment of the spinal type of respiratory failure in poliomyelitis.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29071

PRESENTATION OF CASE

A sixty-five-year-old woman entered the hospital because of "gas around the heart" and palpitation.

Approximately one year before entry the patient developed slight constipation, which was relieved readily with mineral oil or milk of magnesia. Since that time she had had intermittent attacks, that is, two or three times per month, of periumbilical crampy pain, each lasting several hours. These were unrelated to food intake or activity and were sufficiently severe on only one occasion to force her to bed. She had had no recurrence of this pain during the four or five weeks prior to admission. She attributed this to pills prescribed by her physician. However, five weeks before entry she began to suffer with considerable belching and sour eructations. The belching was worse at night and half an hour after meals, but was not otherwise related to activity and was not effected by bowel movements. During this same period, palpitation frequently occurred at night. At no time had there been malaise, anorexia, nausea, vomiting, diarrhea, melena, jaundice, dyspnea, orthopnea or ankle edema.

The family and past histories were noncontributory.

Physical examination revealed a moderately obese, somewhat apprehensive woman who did not appear to be uncomfortable. The chest was barrel shaped. Examination of the lungs was negative. The heart was considered enlarged to the left; the sounds were of good quality and no murmurs were audible. The abdomen was soft. There was slight tenderness and a poorly defined mass in the left lower quadrant.

The blood pressure was 167 systolic, 90 diastolic. The temperature was 97.6°F., the pulse 88, and the respirations 18.

The examination of the blood revealed a hemoglobin of 14.7 gm. and a white-cell count of 9700 with 69 per cent polymorphonuclear leukocytes. The urine was normal except for a rare white and epithelial cell in the sediment. A gas-tic analysis revealed no free acid in the first

specimen and 15 units in the specimen collected an hour later. The gastric contents were guaiac negative. Repeated stool examinations were guaiac negative. A Graham test was negative. A barium enema showed narrowing and marked mucosal swelling of the midportion of the sigmoid over a distance of approximately 10 cm. Definite ulceration of the mucosa was not visible. There were numerous diverticula in the sigmoid and descending colon. The colon proximal to the lesion was not examined. Ten days later the barium studies were repeated, barium being introduced by means of a Foley catheter. At this examination there was complete obstruction in the sigmoid in the area of greatest narrowing previously described. The exact nature of the lesion could not be demonstrated because insufficient barium passed the point of obstruction.

An operation was performed on the sixteenth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. REGINALD M. SMITHWICK: The history indicates that this sixty-five-year-old woman had had symptoms referable to the gastrointestinal tract for about a year. One of these was slight constipation, which apparently did not increase in severity and was easily relieved by nondrastic laxatives. There were also short periods of crampy abdominal pain occasionally lasting several hours. Later, belching and sour eructations but no nausea or vomiting were noted. There was no distention, increased peristalsis or fever. An indefinite, slightly tender mass in the left lower quadrant tends to incriminate the large intestine. This was confirmed by a barium enema, which revealed a process involving the midportion of the sigmoid—with marked narrowing on the first examination and complete obstruction on a second examination ten days later. There is no evidence in the history of other clinical signs of complete obstruction, such as distention, pain, increased peristalsis, nausea and vomiting. Apparently her bowels moved in spite of the x-ray evidence of marked obstruction, since it is reported that repeated stool examinations were negative for occult blood.

The question for discussion seems to be the nature of the lesion in the sigmoid colon. The x-ray suggests an intrinsic process. A review of the films may be helpful.

DR. GEORGE W. HOLMES: There is nothing of interest in the chest. The gall bladder is well seen and looks normal. The colon is obviously abnormal, and the picture is characteristic of diverticulosis, with multiple large diverticula scattered throughout the descending colon and sigmoid.

At one examination there was no definite obstruction. At another examination ten days later there was definite obstruction. At the first examination, in addition to the diverticulums, there was evidence of spasm. The film taken in the lateral view shows a good outline of the lumen of the large bowel, and it does not seem possible that a tumor large enough to plug the bowel could have been present and have been completely missed at this first examination. At the second examination the filling is insufficient and one could miss a tumor, but I should not expect a large tumor to appear in such a short interval. So far as the x-ray demonstration goes there was no ulcerated lesion or tumor, so our interpretation would be that the obstruction was due to the diverticulitis.

DR. SMITHWICK: The two most likely diagnoses are carcinoma and diverticulitis, with or without a localized perforation and abscess. It is possible that both lesions were present. These seem more probable explanations for the sigmoid lesion than tuberculosis, lymphoma, endometriosis, metastatic carcinoma or the extension of a primary lesion of the left uterine adnexa to the bowel. There is no evidence of a benign polypoid tumor of the bowel.

With regard to the differential diagnosis between cancer and diverticulitis, it is at times easy, at times difficult, and occasionally impossible. The age of the patient is not helpful, since either lesion is probable at sixty-five; and the duration of symptoms is quite in keeping with either diagnosis. The absence of clinical symptoms of increasing constipation favors a diagnosis of diverticulitis, whereas the x-ray evidence of complete obstruction leads one to favor cancer, particularly if it persisted after a few weeks of proximal decompression of the bowel. The location of the lesion—the sigmoid area—is a characteristic one for both carcinoma and diverticulitis. The absence of blood in the stools is definitely in favor of diverticulitis, since bleeding is present in only about 16 per cent of the cases of diverticulitis and usually occurs in cases of cancer. The presence of a mass is not helpful. Even at operation one often cannot differentiate the two lesions by inspection or palpation. The pathologist has to decide the matter following resection of the involved area. The x-ray evidence obtained from the first barium enema favors diverticulitis because of the long segment involved (10 cm.) and the absence of destruction of the mucosa. The presence of both lesions is statistically unlikely, as diverticulums have been found associated with carcinoma in only 0.6 per cent of cases, whereas cancer has been found associated with diverticulitis in only 1.8 per cent of cases.

It seems to me that the evidence at hand favors a diagnosis of diverticulitis of the sigmoid with a recent increase in the inflammatory process; an associated localized perforation is a reasonable explanation for the recent x-ray evidence of complete obstruction.

DR. TRACY B. MALLORY: If you had a choice between the two alternatives, Dr. Holmes, which would you choose from the x-ray point of view?

DR. HOLMES: There is no x-ray evidence of tumor. If we made the diagnosis from the x-ray examination alone we should have to say diverticulitis.

CLINICAL DIAGNOSIS

Diverticulitis.

DR. SMITHWICK'S DIAGNOSIS

Diverticulitis of sigmoid.

ANATOMICAL DIAGNOSES

Carcinoma of sigmoid.

Diverticulosis.

PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was operated on and a segment of the sigmoid was found to contain many large and deep diverticulums. The involved segment was moderately firm. The surgeon's preoperative diagnosis was diverticulitis. When he finished the operation he apparently wavered a bit, since he raised the question of carcinoma; but he still put down diverticulitis as his first diagnosis.

When the sigmoid was opened in the laboratory, a small annular cancer was found in the midst of the segment, which had caused a significant grade of obstruction. We could find no evidence that any of the diverticulums were inflamed, and we thought that they were purely coincidental and that the symptoms were due to carcinoma.

DR. SMITHWICK: How do you explain the difference in the barium enema in ten days?

DR. MALLORY: There might have been enough difference in the pressures used during the two examinations.

DR. HOLMES: So one got through and the other did not? I hardly think so. Where was the cancer?

DR. MALLORY: In the midst of the area of diverticulosis in the sigmoid.

DR. HOLMES: At the second examination the obstruction does not seem to be abrupt, and I wonder if they failed to get the enema in.

CASE 29072

PRESENTATION OF CASE

A thirty-three-year-old man was admitted because of nausea, vomiting, stiff neck and headaches.

Three weeks prior to admission he developed a stiff neck. This was followed ten days later by the onset of severe headaches and then by nausea and vomiting. He soon began to vomit continuously, and was unable to retain anything so that during the week prior to admission he had had no fluids or solids by mouth. Five days before entry he entered a community hospital, where he was found to be afebrile and weak. He became drowsy and lapsed into coma. He was treated with intravenous fluids. A lumbar puncture revealed an initial pressure of 235 mm. of water, and after removing 10 cc. of clear fluid, the pressure was 100 mm.; there were 3 cells per cubic millimeter. Examination of the blood showed a white-cell count of 9200, a red-cell count of 4,000,000 and a hemoglobin of 76 per cent. The coma persisted until the evening prior to admission to this hospital.

The patient was known to have Huntington's chorea, as did his mother and maternal grandmother. For a number of years he had had involuntary twitches and sudden movements of both arms. He was able to sit quietly, but staggered drunkenly when he walked; he had recently had urinary incontinence. Thirteen years before entry, following a blow to the back of the head, he was said to have suffered concussion. Eight years later he injured his head but was not rendered unconscious. He frequently bumped his head and injured himself.

Physical examination revealed a well-developed, dehydrated semicomatose man lying in bed with his neck hyperextended and stiff, and breathing slowly and deeply through the mouth. The tongue and mucous membranes of the mouth were dry, crusted and caked. The right eye blinked continuously. Both eyes were held with the gaze upward and to the right, although the patient was able to move them voluntarily. The fundi were normal. Examination of the heart was negative. There was dullness with absent breath sounds at the right lung base posteriorly, and a few moist rales were audible at the left base posteriorly. No masses were felt in the abdomen. There was a continuous tremor of the left forearm and the fist was tightly clenched. The tendon reflexes were active. The abdominal and cremasteric reflexes were absent. The Babinski reflex was positive on the right. No clonus could be demonstrated.

The blood pressure was 110 systolic, 80 diastolic. The temperature was 101°F., the pulse 100, and the respirations 25.

The examination of the blood revealed a red-cell count of 5,570,000 with a hemoglobin of 14.6 gm. and a white-cell count of 18,250 with 90 per cent polymorphonuclear leukocytes. The urine was acid in reaction, had a specific gravity of 1.030 and gave a ++ test for albumin; the sediment contained innumerable red and white cells. The urine was unchanged when examined on the succeeding two days. The blood Hinton test was negative. A blood culture revealed no growth. The blood nonprotein nitrogen was 34 mg. per 100 cc., the chloride 115.8 milliequiv. per liter, the total protein 6.8 gm. per 100 cc., the calcium 10.8 mg., and the phosphorus 4.0 mg. A lumbar puncture showed an initial pressure of 110 mm. of water; no cells were found in the spinal fluid, and the gold-sol curve was normal; the protein was 27 mg. per 100 cc. The spinal-fluid Wassermann test was negative. An x-ray film of the chest demonstrated a mottled consolidation in the right lower lung field; there were old scars in the right apex.

The patient was treated with parenteral fluids, and a total of 5 gm. of sodium sulfadiazine was administered intravenously on two days without noteworthy effect. The blood sulfadiazine level on the third hospital day was 4.1 mg. per 100 cc.; the bicarbonate was 25.6 milliequiv. and the chloride 107.7 milliequiv. per liter, and the nonprotein nitrogen was 26 mg. per 100 cc. The patient died on the fourth day after admission.

DIFFERENTIAL DIAGNOSIS

DR. MANDEL E. COHEN: To summarize this history briefly, the patient was a young adult who had Huntington's chorea, and it is said that his family had the same trouble. Twenty-one days before admission he had a stiff neck. Ten days before, he had nausea, headache and vomiting and could take nothing by mouth. Five days before, he became drowsy, lapsed into stupor, then coma and apparently when admitted to this hospital was comatose, in fact, we may say he was moribund.

Did the patient have Huntington's chorea, or was that an erroneous diagnosis? All we can do is accept the diagnosis, as it is a well-known syndrome and was present in the patient's family. He was a bit young to have it so far developed, but that is quite all right.

The next question is, Is the incident which led to the patient's death one that is explained by Huntington's chorea, and was it the natural

development of the illness? The answer to that I should say is, No. Patients with uncomplicated Huntington's chorea do not develop sudden acute changes in the central nervous system that cause headache, stiff neck, vomiting and so forth. So I think we shall have to postulate that some other disorder complicating the Huntington's chorea led to the patient's illness and death.

Does the fact that the patient had Huntington's chorea in any way alter the history and the examination? I should say that that certainly is a possibility, because if this man had considerable cerebral change, with psychologic symptoms, it would have been difficult to obtain an accurate history either from him or from his family. Furthermore, the patient probably first consulted his physician late in his illness. There are two other consequences of Huntington's chorea that should be mentioned in connection with this case: one is trauma, and the other is suicide. These patients frequently fall down. A case is recorded in which a man suddenly spun around and fell into a plate-glass window. Another patient, standing near a flight of stairs, had one of the jerky movements of Huntington's chorea, fell over backward and was killed. Suicide is of high incidence in this group, and the question might be raised whether this man had taken some poison, such as bichloride of mercury. We have no evidence for that, but I think we must keep the possibility of trauma in mind, particularly since we are told that he had hurt himself in the past.

I shall assume that some intracranial difficulty led to the patient's final illness and death and that it was a fairly acute process—not something that came as a natural development of Huntington's chorea. There are two good possibilities: one is neoplasm, and the other is subdural hematoma.

In addition we should consider the other types of disease that commonly occur in the brain. First, did the patient have a vascular lesion? Against that are his age and the slow onset. Furthermore, he had no other evidence of vascular disease—no high blood pressure or blood in the spinal fluid. Did he have an infectious lesion in the brain? Here again we do not have evidence for that sort of diagnosis. There was no obvious primary focus of infection. The record states nothing about the ears or sinuses, but I shall assume that they were examined and were normal. He did have a pulmonary lesion, which was detected when he was here but not at the first hospital. Without any further information, I must interpret that as a terminal bronchopneumonia. Against infection are the facts that he was afebrile, that the white-cell count was normal and that the spinal fluid on two occasions showed no cells or elevated protein.

I suppose he could, as a remote possibility, have had a brain abscess, but we have no evidence in that direction. Hence, infection was probably not the cause of this man's difficulty.

So that still leaves us with the two possibilities previously mentioned. He probably had a mass of some kind, either a tumor or a subdural hematoma. There is not enough evidence to localize the lesion accurately. Two localizations fit some of the facts, but neither fits all of them. One is that the mass was in the posterior fossa. In favor of that is the fact that the patient had a stiff neck, headache and abnormalities of head posture and eye movements; against it is the fact that the intracranial pressure was not particularly elevated, since the optic disks were not choked. There is some evidence for a more anterior lesion, such as one in the left cerebrum, since the right eye blinked continuously. He had a positive Babinski sign on the right side and tremors on the left—not on the right. One might say that the tremors were due to the chorea and the left-sided lesion had stopped the tremors, but that is just speculation.

I should say that in treating this patient burr holes should be made for a subdural hematoma and that if this were not found a tumor should be looked for. But in making the diagnosis I should place neoplasm first and subdural hematoma second.

If this was a tumor, was it primary or secondary? Metastasis might have occurred from a tumor of the lung. We do not know whether the lesion at the right lower base was due to pneumonia or whether there was some evidence of tumor. In addition, we have not explained satisfactorily the red cells in the urine. Did he have a bladder tumor, which would also account for the incontinence? If we can believe the history, the illness started out of a clear sky with a stiff neck; the red cells were probably due to catheterization on several occasions.

At autopsy, we shall probably be told that in the brain there were the changes characteristic of Huntington's chorea, with atrophy of the cortex and of the caudate nuclei, together with a primary neoplasm, possibly a glioma, which I cannot localize or with a subdural hematoma, and with bronchopneumonia and cystitis.

DR. AUGUSTUS ROSE: The importance of a stiff neck in pointing to infection of the central nervous system is worth discussion. Dr. Cohen has assumed that it does not necessarily indicate infection. I should like to ask Dr. Cohen to discuss the mechanism of stiff neck in posterior-fossa tumors.

DR. COHEN: I do not know, and there is no final evidence in the literature. I suppose the general explanation is that such a stiff neck means irritation of the tentorium, which in turn causes the extensor reflexes of the neck to be stimulated; this can occur either with a lesion in the posterior fossa or with a mass in the brain that acts by pressure or herniation.

DR. ROSE: Do you consider this a kind of decerebration?

DR. COHEN: Yes.

CLINICAL DIAGNOSES

Huntington's chorea.

Bronchopneumonia.

Encephalitis?

DR. COHEN'S DIAGNOSES

Huntington's chorea.

Brain tumor (? glioma) or subdural hematoma.

Bronchopneumonia.

Cystitis.

ANATOMICAL DIAGNOSES

(Huntington's chorea.)

Subdural hematomas, bilateral, massive.

Bronchopneumonia, confluent, right lower lobe.

Cystitis, acute hemorrhagic, marked.

PATHOLOGICAL DISCUSSION

DR. CHARLES S. KUBIK: There was a large subdural hematoma on each side, the one on the left

being the larger. Since the membranes surrounding the hematomas were fairly dense, the lesions were probably several months old. There was a large temporal pressure cone on the left side, and a smaller one on the right, with resulting compression of the midbrain and aqueduct. There were hemorrhages in the midbrain, a common finding with a temporal pressure cone. Compression of the midbrain and aqueduct probably caused an actual dynamic block, which accounted for the low spinal fluid pressure (110 mm.). Removal of fluid by lumbar puncture would have a tendency to make a bad situation worse by allowing the pressure cone to herniate farther. Pressure against the midbrain or stretching of the tentorium or both may also have had something to do with the stiffness of the neck.

Other changes, presumably related to the Huntington's chorea, were marked atrophy of the caudate nuclei, diminution in the size of the lenticular nuclei and enlargement of the lateral and third ventricles.

Flattening of the cortex by the hematomas made it difficult to estimate the degree of cortical atrophy.

DR. TRACY B. MALLORY: There was a well-marked cystitis, which was certainly the cause of the red cells in the urine and probably the result of catheterization. The lungs showed diffuse congestion and edema, with an area of bronchopneumonia at one base.

MATERIAL for early publication should be received not later than noon on Friday.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fennway, Boston, Massachusetts.

THE VICISSITUDES OF WAR

For the duration of the war the *Journal* has been obliged to adopt changes that are not of its own choosing. Paper is becoming scarce and all publishers of periodicals who buy more than a certain tonnage each quarter have been limited by the War Production Board to 90 per cent of the paper used in 1942. Furthermore, owing to the need for chlorine in the manufacture of munitions and other war materials, the good grades of paper pulp are unobtainable. In addition, the scarcity of manpower is a distinct handicap to the typesetter, the printer, the binder and the mailer. And, finally, the entrance of so many physicians in and around

Boston into the armed forces, particularly young men, who are apt to be engaged in clinical or experimental investigative work, has resulted in a marked reduction in the number of contributors to the *Journal*; whereas those who remain at home, for one reason or another, are so deluged with extra duties that the writing of a paper, which to almost everyone is a chore, is necessarily, and probably thankfully, put aside. A reasonable number of papers are still being submitted for publication, but the members of the editorial board are unanimous in their belief that quality should not be sacrificed for quantity—in other words, that the high standards for acceptance should not be lowered.

In the future, the readers of the *Journal* must be content with receiving, somewhat tardily, a periodical of smaller size and one that is printed on a poorer grade of paper. It is anticipated that the two weekly features, "Medical Progress" and the "Case Records of the Massachusetts General Hospital," can be continued, but original articles, like sugar and coffee, must be rationed. For all this, the *Journal* apologizes, but asks that its subscribers accept these unavoidable changes with the same spirit that they have shown regarding the many real sacrifices entailed by the war effort.

PROPHYLACTIC SULFONAMIDE THERAPY

MECHANIZED warfare and rapidly changing areas of combat often preclude immediate definitive surgical care of war wounds and burns. Various combinations of general and local sulfonamide therapy have been suggested as part of the first-aid routine to delay or prevent the onset of infection during the period of evacuation to competent surgical stations. The British experience at Dunkirk and in the Middle East has established certain facts: wounds filled with sulfanilamide are protected from infection for three to five days only; local sulfanilamide does not prevent staphylococcal wound infection; and wounds excised primarily

heal more kindly than those treated with sulfanilamide and delayed surgical care.¹

Current experiments are seeking means of prolonging the effect of topically applied sulfonamides and of potentiating sulfonamide action against the staphylococcus. Hawking² has used various sulfonamide pastes to prevent bacteremia in experimental hemolytic streptococcus infection of wounds in rabbits. Sulfanilamide in an oily base was therapeutically superior to watery suspensions of the drug. However, cod-liver oil caused an especially undesirable tissue reaction, liquid paraffin was moderately bad, and even cottonseed oil, the least harmful, had some ill effect. The most successful results were obtained with a suspension in physiologic saline solution of microcrystals of the relatively insoluble sulfathiazole.

Goldberger³ has reported a potentiated sulfonamide action as a consequence of combination with oxidant antiseptics. Schmelkes and Wyss⁴ and Neter⁵ have demonstrated that chlorine inactivates the inhibitory effect of para-aminobenzoic acid. This same group of investigators⁶ has advanced the hypothesis that the antibacterial effort of sulfonamides is a manifestation of the action of the anionic or zwitterionic species of free dissociated sulfonamide. Inasmuch as all the sulfonamides are weak acids, it has been proposed that a relatively insoluble buffer, such as calcium carbonate, be added to sulfonamide preparations in order to maintain a pH optimal for free dissociation and maximal antibacterial effect. Urea and wetting agents of the triethanolamine type have also been suggested as a means of increasing the solubility and dispersion of topically applied sulfonamides.

Increasing clinical experience with locally applied sulfonamides has recorded instances of excessive absorption of the drug from large wounds and extensive burns. A high blood level of sulfonamide is particularly dangerous when there is depression of renal function from shock or dehydration. Foreign-body reactions and occasional cases of intestinal obstruction have followed the intraperitoneal use of sulfonamides other than the

fairly soluble sulfanilamide. The early reports of the treatment of appendiceal peritonitis with subcutaneously and orally administered sulfanilamide have not been significantly bettered as a consequence of the intraperitoneal use of sulfanilamide. There remains the possibility that the success of local applications depends to some extent on the systemic absorption of the drug.

There is every reason to believe that oral or parenteral sulfonamide therapy offers the most effective control of invasive streptococcal infection. Local sulfonamide therapy introduces a factor of uncontrolled drug absorption, and a deleterious effect on wound healing has been reported. Hence it would seem preferable that civilian injuries receive prompt definitive surgical attention and systemic sulfonamide without local drugs. Local chemotherapy should be reserved for those exigencies of battle wherein no other therapy is possible.

MEDICAL EPONYM

STILL'S DISEASE

George Frederick Still (b. 1868), medical registrar and pathologist to the Hospital for Sick Children, Great Ormond Street, London, contributed a paper, entitled "On a Form of Chronic Joint Disease in Children," to the Royal Medical and Chirurgical Society of London on April 23, 1896. The communication was read by Dr. Archibald E. Garrod on November 10, 1896, and appears in the society's *Medico-Chirurgical Transactions* (80: 47-59, 1897).

There is a disease, occurring in children, and beginning before the second dentition, which is characterised clinically by elastic fusiform enlargement of joints without bony change, and also by enlargement of glands and spleen.

This disease has hitherto been called rheumatoid arthritis, but it differs from that disease in adults, clinically in the absence of bony change, even when

the disease is advanced, and in the enlargement of glands and spleen, and pathologically in the absence, even in an advanced case, of the cartilage changes which are found quite early in that disease, and also in the absence of osteophytic change.

These differences are not to be attributed merely to modification of disease by difference of age, as there occurs also in children a disease in every respect identical with the rheumatoid arthritis of adults.

DEATH

EASTON—ELWOOD T. EASTON, M.D., of Boston, died January 31. He was in his sixty-eighth year.

Born in Rockland, he received his degree from Harvard Medical School in 1899. He became ophthalmic surgeon at the Massachusetts Eye and Ear Infirmary, instructor in ophthalmology at Tufts College Medical School and later professor of that department. He was a member of the Massachusetts Medical Society, the American Medical Association and the New England Ophthalmological Society and held the certificate of the American Board of Ophthalmology.

His widow, three sons, three daughters and three grandchildren survive him.

GATES—ERNEST A. GATES, M.D., of Springfield, died January 4. He was in his seventy-fourth year.

He was a member of the Massachusetts Medical Society, the American Medical Association and the Springfield Medical Club.

His brother and two sisters survive him.

ROBBINS—EUGENE STANLEY ROBBINS, M.D., formerly of New Bedford, died January 18 at West Palm Beach, Florida. He was in his seventy-first year.

Born in Plymouth, Connecticut, Dr. Robbins received his degree from the Bellevue Hospital Medical College, New York, in 1893. He then did postgraduate work in Paris and Berlin. Dr. Robbins was a member of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

WAR ACTIVITIES

CIVILIAN DEFENSE

BLOOD-PLASMA RESERVE

The Medical Division of the United States Office of Civilian Defense pointed out in a recent medical circular that plasma reserves are available in every Civilian Defense region for use in the event of casualties resulting from enemy action or sabotage. The circular emphasizes that this plasma may be used for lifesaving in any disaster. If this plasma is used in nonwar-related incidents, its employment may be considered as a loan, and arrangements may be made later for its replacement, it is pointed out.

Through monthly reports issued by the blood-plasma section of the Medical Division, regional medical officers keep all chiefs of Emergency Medical Service, hospitals and American Red Cross disaster-relief chairmen informed concerning the amount and distribution of plasma reserves

available in their states, and how localities may secure additional supplies in emergencies.

In cities where reserves are stored, they may be obtained by hospitals through the local chiefs of Emergency Medical Service. If a community is without plasma or if its supplies are depleted, the local chief may obtain additional plasma in emergencies from the state chief of Emergency Medical Service.

MISCELLANY

HEMORRHAGE FROM THE TRACHEA, BRONCHI AND LUNGS OF NONTUBERCULOUS ORIGIN

"Hemoptysis," wrote French, "literally means blood spitting, but clinically it is restricted to the expectoration of blood from the lungs, bronchi or trachea." Fifty years ago it was pathognomonic of tuberculosis, with mitral disease as the runner up. These two still dominate the field of etiologic possibilities. It has remained for the bronchoscopist (Jackson, C. L., and Diamond, S. Hemorrhage from the trachea, bronchi and lungs of nontuberculous origin. *Am. Rev. Tuberc.* 46:126-138, 1942) to show us the prominent roles played by other conditions.

The spitting of blood is, of course, the presenting symptom in many and diverse conditions, so the need for painstaking detailed diagnostic study cannot be stressed too strongly. Short cuts and diagnoses by inference are to be condemned.

First, it is necessary to eliminate hematemesis. Useful here is the fact that blood from the lower respiratory tract is usually frothy and bright red, and apt to be mixed with bronchial secretion, whereas that from the stomach ordinarily is dark and often contains particles of food. It should also be noted that in cases of massive hemorrhage, pallor and loss of consciousness are likely to precede a hematemesis whereas in bronchopulmonary bleeding the blood almost invariably is expectorated before signs of actual blood loss appear.

Having by history and careful physical examination eliminated hematemesis and obvious lesions of the larynx and nasal, oral or pharyngeal cavities, one must assume that the source of the blood is subglottic. It is important to note here that the authors believe that, "far too much emphasis has been placed upon varicose veins at the base of the tongue as hemorrhagic foci." (Not a single case was found in their series.)

Once it is determined that the blood is coming from the lower respiratory tract, tuberculosis is the likeliest diagnosis; to quote the authors, "The disease masquerades under many and varied guises." The inquiry must be considered incomplete until the tuberculous or nontuberculous nature of the underlying lesion has been established beyond question.

Tuberculosis having been ruled out, and cardiovascular disease, the blood dyscrasias and acute lobar pneumonia having been eliminated, the search becomes more difficult.

Precise localization and identification of the causative lesion are dependent on supplementary procedures. A comprehensive fluoroscopic and roentgenographic examination of the chest, including planigraphy and bronchography when indicated, is in order in every case of hemoptysis, as well as bronchoscopy, if necessary. As to the advisability of bronchoscopy a patient during or immediately following a hemorrhage, the authors believe that streaking of the sputum is not a contraindication, but

that when frank hemoptysis has occurred, bronchoscopy should not be performed until several days have elapsed since its cessation

What now are the etiologic probabilities? The authors indicate them in the accompanying table, which shows the results of careful diagnostic study of 436 patients re-

Tracheal, Bronchial and Pulmonary Lesions Found in 436 Patients with Hemoptysis

NATURE OF LESION	NO OF PATIENTS IN EACH AGE GROUP AT TIME OF INITIAL HEMOPTYSIS									TOTAL NO OF PA- TIENTS

Totals	25	41	97	82	76	82	33		436	

ferred for bronchoscopy In the interpretation of this table, it is important to note the following comment of the authors

A great many patients admitted to the hospital with pulmonary bleeding are not seen by the bronchoscopist, the nature of the underlying disease being such that no indication for the direct inspection of the tracheo-bronchial tree is present Included in this category are patients with cardiovascular lesions which lead to the production of chronic passive congestion or pulmonary infarction, patients with acute lobar pneumonia, and patients with blood dyscrasias This group, observed by the internist alone, represents a considerable number of patients with hemoptysis

The authors make the following conclusions

Inflammatory processes are responsible for the hemoptysis in the majority of the cases, the most common etiologic agent being bronchiectasis When one takes into consideration the fact that expectoration of blood is the initial manifestation of carcinoma of the bronchus in only a very small percentage of the patients, it is obvious that bronchoscopy must be done and the diagnosis made early in the course of the disease, before the symptoms have reached the stage of hemorrhage, if a successful therapeutic result is to be achieved in these cases.

Fatal hemorrhage occurred in but 3 of the patients in the series, each of whom had a pulmonary abscess—Reprinted, in part, from *Tuberculous Abstracts* (February, 1943)

ANNUAL PRIZE SUBSCRIPTION

The annual prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts Medical Journal* has been awarded to E Allen Joslyn, '44, for his paper 'Fat Metabolism in Relation to Diabetes,' which appeared in the December, 1942, issue. The paper, 'Cardiac Surgery,' by Mauray Tye, '43, received honorable mention, it appeared in the October, 1942, issue of the journal

BOOK REVIEWS

Surgery of the Ambulatory Patient By L. Kraeger Fergusson, M.D. With a section on fractures by Louis Kaplan, M.D. 8°, cloth, 923 pp., with 645 illustrations Philadelphia J B Lippincott, 1942 \$10.00

The purpose of this book is clearly announced in the challenging statement of the authors, 'It is probable that more poor surgery is performed on minor lesions of the hand than for instance, on major brain lesions' For the surgeon who has mastered the technique of major surgery, much of the general discussion is superfluous But this book will be of greatest help to the general practitioner who only does surgery on minor cases and in whose hands a minor operation may become a major disaster if certain precautions are not followed

Although many of the procedures described may be done on office or hospital outpatients, some are better reserved for hospital inpatients The author states that he has ligated over two hundred saphenous veins as an office procedure. Some surgeons are emphatic in their insistence that this should always be done in the hospital as a full-dress operation However, this is in no way a criticism of the basic material in the book, which is eminently sound The division into symptoms, pathology, diagnosis and treatment makes each section easy to follow, and the illustrations are so well chosen and in such numbers that one can often follow the author by means of them, without reference to the text.

In a work such as this, one hesitates to single out any one portion as superior to the others However, the considerations of breast pathology, low back pain and varicose veins are so good that they seem to deserve special mention

Ambassadors in White The story of American tropical medicine By Charles M Wilson 8°, cloth, 372 pp., with 42 illustrations New York Henry Holt and Company, 1942 \$3.50

The story of American tropical medicine is told by Wilson in an exciting and enthusiastic style Most of the story will be news, not only to the layman but also to the physician who does not know the tropics The names of Gorgas, Walter Reed and Noguchi are familiar to all, but how many of us have more than an inkling of what they did? Still fewer know about the pioneering of Finlay in yellow fever or have heard of the great medical service built up by Deeks for the United Fruit Company

In his first chapter, Wilson emphasizes the transcendent significance of disease in tropical America Although what the author says is true of the peons in certain primitive and unsanitized regions, it is not true of the great cities of Latin America or of the more cultured elements of the population In other chapters the health problems

arising from a few of the more important diseases of the tropics are presented briefly. There are also vivid sketches of outstanding personalities upon whom praise has been generously bestowed. A few inaccuracies of no great importance were noted by the reviewer, and some of the information about disease is out of date.

The reviewer regrets being obliged to point out that on pages 200, 201 and 202, in his sketch of Noguchi's work, Wilson has criticized unfairly the research of a Harvard expedition to Peru. Not only has the author been ill-informed, but the tone of some of his remarks is offensive. Noguchi would never have assumed this attitude. Noguchi, moreover, would have recognized the fact that, at a time when his *Leptospira icteroides* had received general acceptance as the cause of yellow fever, skepticism persisted at Harvard. This skepticism culminated in a series of well-planned experiments by Sellards and Theiler which proved beyond a shadow of doubt in 1926 and 1927 that *Leptospira icteroides* and *L. icterohaemorrhagiae* were identical, and that a leptospira was not the cause of yellow fever.

Theiler, M., and Sellards, A. W. The relationship of *L. icterohaemorrhagiae* and *L. icteroides* as determined by the Pfeiffer phenomenon in guinea pigs. *Am. J. Trop. Med.* 6:383-402, 1926.

Sellards, A. W., and Theiler, M. Pfeiffer reaction and protection tests in leptospiral jaundice (Weil's disease) with *Leptospira icterohaemorrhagiae* and *Leptospira icteroides*. *Am. J. Trop. Med.* 7:369-381, 1927.

Sellards, A. W. The relation between Weil's disease and yellow fever. *Ann. Trop. Med.* 21:245-259, 1927.

Acute Injuries of the Head: Their diagnosis, treatment, complications and sequels. By G. F. Rowbotham, B.Sc. (Manch.), F.R.C.S. (Eng.). With a foreword by Norman M. Dott, M.B., Ch.B. (Ed.), F.R.C.S. (Ed.). 8°, cloth, 288 pp., with 124 illustrations. Baltimore: The Williams and Wilkins Company, 1942. \$7.50.

"This book is written primarily for those who are responsible for the treatment of acute cerebral trauma and who have not received special training in neurosurgery or neurology." Every hospital must care for patients with acute craniocerebral injuries, and usually the small institutions do not afford good treatment because of a disinterested profession. It is essential that general surgeons who are called on to treat such patients know the main points of diagnosis on which treatment is based. They should recognize the indications for exploration of the cranial vault, for subtemporal decompression and for the treatment of compound fractures of the skull. This book furnishes a concise review, which may serve as a guide to the correct handling of craniocerebral injuries.

There are some well-chosen illustrations on operative technic. The last chapter, "Sequels of Head Injuries," is the best of the whole book. This aspect is one of the most important but often most neglected of the entire subject. The description of the post-traumatic syndrome could not be better done than it is in the author's depiction of such a patient in the physician's office.

A few items in the book deserve mention because of their variance with American practice. The author does not encourage, but he does allow, the use of morphine after head injuries in ¼-gr. doses; whereas in this country the drug is considered to be absolutely contraindicated in

such cases. In the author's experience of 25 cases of middle meningeal hemorrhage, all had a lucid interval; the many exceptions to this are not stressed sufficiently. It is stated that patients with craniocerebral injuries can usually be up and about in three weeks, with gradual mobilization during this period. In the reviewer's experience, probably no single factor can prevent development of the postconcussion syndrome more than absolute rest in bed; in severe injuries this should be continued for at least three weeks, and as long after that as symptoms are present.

Handbook of Health for Overseas Service. By George C. Shattuck, M.D., with contributions by other authors. 24°, cloth, 198 pp., with 14 illustrations. Cambridge, Massachusetts: Harvard University Press, 1942. Not for sale (copies may be obtained gratis from the Harvard University Press).

This volume was prepared for the Co-ordinator of Information, Washington, D. C., now known as the Office of Strategic Services. Its purpose is to act as a guide for nonmedical men who travel in places where medical services are not available. It covers such subjects as food, drinking water, camp hygiene, clothing and first aid, with a brief discussion of many diseased conditions that may be encountered. Although all diseases are not included, it is reasonably comprehensive, covering ailments of the tropical and arctic regions. A list of the drugs and surgical equipment that should be available are included, although these necessarily are limited in number.

The volume is compact, has a flexible cover and can easily be carried in the pocket. It should be of great value to men going on field service and can safely be recommended by the physician to patients so situated that immediate medical attention is not available.

Doctor Bard of Hyde Park: The famous physician of Revolutionary times, the man who saved Washington's life. By John B. Langstaff. Introduction by Nicholas M. Butler. 8°, cloth, 365 pp., with 11 illustrations and frontispiece. New York: E. P. Dutton and Company, Incorporated, 1942. \$3.75.

This is a carefully written and well-documented life of one of the outstanding Revolutionary physicians who practiced in New York City during the latter part of the eighteenth century. He was a physician at one time to George Washington and served as president of the College of Physicians and Surgeons. He later retired to Hyde Park on the Hudson, and the title of the book is taken from this relatively unimportant period of his life. The interest in Bard is largely through the development of the New York Hospital, his operation on George Washington for a severe carbuncle and the pleasant stamp that he gave to medicine during his time. He was an excellent example of the English gentleman physician, in direct line with Lettsom and Fothergill. The author has done an excellent piece of work in collecting the data. He has long been associated with the medical profession for he has served as chaplain of the Bellevue Hospital and is the son of a well-known physician. He descends, moreover, from physicians who were active in New York in Bard's time. This is an important biography and should be widely read.

VASCULAR AND NEUROLOGIC LESIONS IN SURVIVORS OF SHIPWRECK

II. Painful Swollen Feet Secondary to Prolonged Dehydration and Malnutrition

COMMANDER JAMES C. WHITE (MC), USNR

BOSTON

THE true immersion-foot syndrome described in the first part of this paper¹ is caused by direct thermal injury to the tissues short of actual freezing. It develops after relatively brief periods of contact with water at temperatures below 50 or possibly even 60°F. A superficially similar, but fundamentally quite different, condition has developed after exposure to warm water and bright sunshine in survivors of torpedoed vessels who have been adrift in the Gulf Stream without an adequate supply of water and food for periods of over two weeks. These individuals may show no evidence of direct cutaneous injury, but yet complain of an equal degree of edema and sensory disturbance. This condition has also been called "immersion foot," but the term is inappropriate in this connection and should be given up.

The cases on which this report is based were seen in a United States Marine Hospital, through the courtesy of Captain W. S. Bean, the commanding officer, a member of the United States Public Health Service. He and his staff have permitted me to add the results of their clinical findings to my own, as well as to make use of their laboratory determinations. The deductions drawn from these data are my own and do not necessarily represent the views of the United States Public Health Service. These survivors of two lifeboat crews have already been the subject of a more detailed report for the Medical Corps of the United States Navy,² which will be briefly summarized here in order to point out that there are two fundamentally different conditions that may lead to much pain and incapacity following the sinking of ships at sea in the present war. Since the more complete report was written, new clinical and laboratory data have been furnished me by Drs. Richard H. Smith and Leo Waitzkin of the United States

Public Health Service. This has necessitated a number of minor changes in the evidence presented and in the conclusions to be drawn therefrom.

It should be emphasized at the outset that the syndrome reported here is different in many respects from that observed after immersion in cold water.¹ With these southern survivors, both vessels were torpedoed in relatively warm water (around 70°F) in southern latitudes during the month of April. The men were adrift for sixteen and seventeen days respectively. Owing to the fact that their ships were torpedoed well off the usual trans-Atlantic shipping lanes and they could not hope for early rescue, their allowance of water was progressively reduced from 16 ounces to a bare 5 ounces a day. With the intense sunshine and heat by day, coupled with the hard work of bailing and handling the boats, both crews developed such severe dehydration that they were unable to swallow the concentrated solid ration of pemmican, hardtack and chocolate. After the first few days all that the men were able to swallow was a small amount of malted-milk powder dissolved in their half-cup of water. Three out of six West African Negroes in the crew of lifeboat A drank salt water and died. All the crew members of lifeboat B survived. The men in both boats were so crowded that they were forced to sit close together with their legs dependent and to sleep in this position. After a week adrift under these circumstances nearly all the men noticed that their feet were becoming greatly swollen and numb; in addition they began to have a peculiar tingling and aching sensation in the soles. Some noticed similar symptoms in their hands but of lesser degree. The swelling and sensory disturbances in the legs were distinctly less noticeable in the men who had been able to move about the most. A few who took turns as steersman were able to

¹Released for publication by the Division of Publications of the Bureau of Medicine and Surgery, United States Navy.

stretch their legs out horizontally during their watches; others realized that the circulation in their feet was improved and the swelling was lessened by flexing and extending their feet and toes. A number of the men in lifeboat B who went over the side on several occasions to swim alongside commented on the improvement in the condition of their lower extremities. On finally being rescued, all were deeply tanned, and many had developed cracks and small crusted lesions due to exposure to wind and salt water. When they came aboard the rescuing vessels most of the men found that walking on their swollen feet was difficult, and that without support they lost their balance because of numbness in their feet and loss of sense of position. In addition the majority complained of deep plantar tenderness and pain. These exact complaints are also common in sailors rescued after immersion in cold water.¹ On their arrival at the hospital, all the men were suffering from exhaustion, malnutrition and dehydration.

The crew of lifeboat A had wet feet throughout the entire voyage, as their boat leaked continuously. During the last two days, when they sailed out of the warm water of the Gulf Stream and approached the coast, the temperature of the sea water fell to around 50°F. (below the critical level at which thermal injury can occur). As a result of this exposure several of the men, notably the West African Negroes (Cases 6, 7 and 8), ran a low-grade fever (99 to 101°F.) for several weeks* after rescue and developed changes in their feet characteristic of exposure to cold. These consisted of patches of superficial gangrene, blebs and sluggish circulation in the cutaneous capillary bed, with a subsequent hyperemic phase after rescue. This condition, however, was pronounced only in the Negroes and was much milder than that generally seen after exposure in northern waters.¹ The crew of lifeboat B were exposed to cool air and suffered from cloudy, heavy weather the first five days, so that their clothes were continuously wet. The weather then cleared and by day "the heat became almost unbearable. . . . Relief was obtained by going overside and swimming. Feet were also soaked in buckets of water. . . . Feet were kept dry except when soaked in buckets during heat of day." The crew of this lifeboat were therefore never exposed to water below 70°F. and showed no signs of cutaneous injury from cold.

After examining these men it was at once apparent that their condition differed fundamentally from that of the survivors seen after rescue from the colder waters of the North Atlantic. Although both groups suffered from swollen and painful feet, many of these survivors of shipwreck in rela-

tively warm water did not bear evidence of tissue damage in their feet, and they had other systemic disturbances of a very different nature. These consisted of slight but definite swelling and subjective sensory disturbances in the hands, as well as the more obvious changes in the feet; many of the men were also found to have glossitis and stomatitis, and additional gastrointestinal complaints. The clinical findings observed in the entire series are summarized in Table 1, and the laboratory determinations in Table 2.

As pointed out above, some direct tissue injury from cold undoubtedly occurred in the crew of lifeboat A during the last two days of their voyage, when they left the warm waters of the Gulf Stream. This was definitely not the case in the men of lifeboat B. But with them, and to a large extent with the men of lifeboat A as well, it is evident that other reasons must have accounted for the greater part of the swelling, which often extended to the knees,† as well as the tenderness and other sensory changes, which involved the feet and, in some cases, the hands as well. Other contributory factors which might account for these findings are the following:

(1) *Continued dependency of the legs.* Hypostatic edema is always a factor after a voyage in a crowded lifeboat of prolonged duration when there is no space to stretch the legs out horizontally and men are forced to sleep in a sitting position.

(2) *Hypoproteinemia.* As a result of extreme dehydration, these men had been unable to swallow any solid food after the first few days adrift. In addition, they were forced to row and bail, the energy for which had to be provided from their own tissues. As a result it is not surprising that many were found to have a serum protein below the critical level at which edema develops. The low albumin-globulin ratio in Cases 1 and 7 is of particular significance. From the experimental work of Jones, Eaton and White⁸ on nutritional edema in animals, it is probable that the swelling in the legs of these men was far less marked during the period that they were adrift and critically dehydrated, and that it developed rapidly as they were able to restore their depleted tissue fluids. There was also a progressive fall in serum protein in the course of rehydration, which is well exemplified by the serial determinations made in Case 1.

(3) *Vitamin deficiency.* One is led to speculate whether the intense aching pain and deep plantar tenderness complained of by these survivors during the last week at sea and in the

*In the case of uncomplicated thermal injury to the feet from cold, the febrile reaction usually subsides within thirty-six hours.²

†The changes due to cold water generally involve only the feet and lower third of the legs.²

CASE No.	SEX	EXTENT OF LESION	CUTANEOUS CHANGES	REFLEXES	SENSORY CHANGES	MUSCLE TENDON-ITIS	PAIN	STATUS TITUS	DAY OF DISCHARGE	COMMENT
CREW OF LIFEBOAT A										
1	79	++	Superficial gangrene in toes 5 (4), amputation in toes 1, 3, 4 and 5 (1).	+	Hypaesthesia and tingling in distal half of feet	+	0	++	20th	Patient had severe degree of malnutrition and diarrhea for a month preceding trip. In lifeboat he covered on floor boards without moving. His general condition was precarious at first, he was semicomatose and had diarrhea with occult blood. Thermal injury to the feet was definite.
2	26	+	0	+	0	0	0	0	20th	Patient exercised feet during period of dependency.
3	22	±	Several small areas of necrosis and dequamation	++	Skin of feet and lower legs hypersensitive	0	0	+	31st	Patient exercised feet while in lifeboat, and evidence of thermal injury was not marked. Neuritis appeared within a week, but he developed a severe stomatitis 3 days after rescue, with fever and leukocytosis. This was cured within a week after treatment with vitamin B.
4	32	0 (formerly present)	0	+	Numbness at first when walking, hypaesthesia wore off distally, disappearing in 3 weeks	0	++	0	20th	Patient exercised feet while in lifeboat. Neuritis gone in a week.
5	35	+	0	-	Hypaesthesia receded to toes in 3 weeks	0	0	0	20th	
6	23 Negro	++	Deep cracks and blisters in skin of soles, with eventual sloughing	+	Impossible to evaluate owing to large edema of feet	+	+++	0		Patient exercised feet 3 days. On 1st day severe inflammatory reaction, which receded in 3 days. On 3rd day cold water was used to treat feet for 9 days. Feet were healed after 2 weeks without vitamin therapy.
7	57 Negro	++	Dequamation and epidermophytosis, hands also swollen at first	+	Pain and sensory changes in hands for 2 weeks, receding to distal half of feet present after 3 weeks	-	+	0		Patient's bare feet were in water most of the time. Pain started after 3 weeks. On 5th day severe hyperemia of feet, which receded in 3 weeks. Patient exercised feet 3 days, but it was not cured. Thermal injury was severe, and probably cured.
8	39 Negro	+	0	+	Hypaesthesia at first in ankles, receding to toes in 3 weeks	0	+			Thermal injury to feet, with severe inflammation of feet. Temperature of feet normal. Patient exercised feet 3 days. No vitamin therapy given. Thermal injury was less marked than in cases 6 and 7.
CREW OF LIFEBOAT B										
9	33	0	0		0	0	±	+	14th	Patient exercised at 1st in general condition.
10	44	0	0		Hypaesthesia of feet, subjective changes in hands	+	++	0	14th	Patient exercised but made good recovery.
11	50	R++ L+	0		Hypaesthesia and paresthesia, subjective changes in hands	+	+	+	14th	Neuritis disappeared in 3 days.
12	35	0	Superficial crusted areas due to sun and windburn		Sensation objectively normal but subjectively abnormal in hands as well as feet	+	+	+	14th	Sensory disturbances disappeared before discharge.
13	24	±	0		Sensation objectively normal but subjectively abnormal in hands as well as feet	+	+	+	14th	
14	32	0	0		Distal half of feet hyperaesthetic, hands to lesser degree	+	+	0	14th	Neuritis disappeared in 3 days.
15	25	0	0		Subjectively both hands and feet feel abnormal	+	++	0	14th	Neuritis cleared quickly.

*Crew of lifeboat A examined 3 weeks after rescue, those of lifeboat B, 2 days after rescue.

hospital could be caused solely by edema secondary to dependency and hypoproteinemia. It appears most unlikely that this could have been the case, and it is not possible to explain hypesthesia and ataxia of the feet, and similar sub-

showed normal responses in the 4 patients tested. This is incompatible with the advanced type of neuritis due to long-standing avitaminosis, but in no way rules out the earlier stages, which might occur in such a relatively brief period.

*The figures do not show the striking alterations in the blood and urine which go with severe dehydration, but it must be remembered that these men had already had up to twenty-four hours to restore their depleted body water reserves before any of the above determinations could be made. Other compensatory factors must also be taken into account. Although Cases 2 and 3 show a definite erythrocyte concentration, the anemia that goes with starvation would counterbalance this. All the serum protein levels are low, and would probably have gone lower, as was so in Case 1, if further estimations had been made after the water balance had returned to normal levels. Half the patients still had a urinary specific gravity of 1.025 or higher after nearly a day's unlimited access to water. The blood urea nitrogen level of 24 mg. in Case 1 is distinctly elevated and the figure of 13.3 mg. in Case 7 is not significant, as it was not obtained until three days after rescue. Loss of blood electrolytes was pronounced in Cases 9 and 10. This was presumably caused by excessive sweating with a low salt intake, whereas the patient in Case 7, who had drunk salt water, had a very high level. The ascorbic acid figures in Cases 9 and 10 are not reduced.

†This patient, not included in the study because he had just been operated on for gastric hemorrhage, had the highest prothrombin time observed.

jective disturbances of the hands, on this basis. This picture is more suggestive of a deficiency in the antineuritic factor in the vitamin B complex, such as is seen in alcoholic neuritis. Examination of the knee jerks in these subjects

Further clinical findings that suggest an avitaminosis were the oral lesions. Of the patients examined, Cases 1, 3, 9, 11, 12 and 13 reached the hospital with a nonspecific stomatitis. This consisted of superficial vesicles and ulcers of the

tongue, buccal mucosa, palate and pharynx. In Cases 1, 9 and 12 the sides of the tongue were smooth and reddened, and the patient in Case 13 had suffered from bleeding gums. It is also of interest to note that in 7 out of 9 patients where the feces were examined with the guaiac and benzidine reagents, the tests were at first positive for occult blood (Cases 1, 10, 11, 12, 14, 15 and 16). It is of further interest that in the 3 patients in whom the prothrombin times were determined, there was an increase beyond the normal period of 20 seconds to 40, 27 and 25 seconds, although there is some question concerning the accuracy of these figures. If the values are correct, they denote a definite deficiency in vitamin K, which reached a severe degree in Case 16. This man, who had a history of chronic indigestion, became severely exsanguinated from a bleeding gastric ulcer, which finally necessitated surgical intervention. Another survivor in the same hospital, who had been rescued after a long period adrift in warm water, also suffered exsanguinating gastric hemorrhages, from which he died. It is possible that this bleeding from the gastrointestinal tract, as well as the stomatitis, is related to nicotinic acid deficiency, since ulcerations may occur at any level in the gastrointestinal tract in the deficiency state. Further studies on the role of vitamin deficiency in shipwreck survivors are urgently needed before any definite conclusions can be drawn.

Heretofore, the signs of alcoholic neuritis and pellagra have not been known to occur in as brief a period as a fortnight. In fasting subjects who have been studied for longer periods, sensory changes in the extremities have not been recorded, but these observations have been made on inactive persons. The fact that thiamin, nicotinic acid and riboflavin play an active chemical role in the oxidation of glucose may explain their rapid depletion in these survivors. A depletion of the antineuritic and other components of the vitamin B complex is, therefore, a distinct possibility. It is also possible that the men who suffered the most were in a partially depleted state before their ships were torpedoed and their vitamin intake stopped. This was certainly true in Case 1, but I was unable to discover any evidence of this in the other men.

In order to obtain further information concerning the possibility that vitamin deficiencies arise in such a short period of time, I consulted two authorities on vitamin deficiency, Dr. John B. Youmans, associate professor of medicine at Vanderbilt University School of Medicine, and Dr. W. H. Sebrell, chief of the Division of Chemotherapy of the United States Public Health Service. Dr. Youmans wrote:

Patients with nutritional edema very frequently develop pain and tenderness, and sometimes superficial inflammation (erythema), particularly when the onset is rather abrupt. . . . With a very restricted diet and with hard work, some deficiencies such as that due to vitamin B₁ are believed to develop evidence of the deficiency within a week or so. . . . The stomatitis and glossitis may well represent a combination of a deficiency of the vitamin B complex, including riboflavin plus dehydration. Dehydration is quite important as there is evidence that this precipitates the syndrome of pellagra.

Dr. Sebrell, who subsequently saw some of this group of patients, states that his "impression is that thiamin and nicotinic acid deficiencies are definite possibilities." When further similar cases can be located he is prepared to make special tests to give accurate information about the thiamin and nicotinic acid levels. Examination of the scleras by the slit-lamp for peripheral vascularization and of the lips and mouth by experts in riboflavin and nicotinic acid deficiency will answer this question with certainty.

Unlike the more severe thermal injuries suffered by the survivors of vessels torpedoed in the North Atlantic, where vascular thrombosis and sepsis may necessitate amputation, the peripheral lesions of the cases from southern waters were not serious and required over a fortnight's hospitalization in only 6 cases. Three of these were the West African Negroes who undoubtedly had complicating injuries from immersion in cold water and less evidence of a vitamin deficiency than their Anglo-Saxon crew mates. The possible increased sensitivity of the West African Negroes to cold and their greater resistance to dietary deficiency will be a point of interest for further investigation. In examining the northern survivors I had been impressed by the fact that the reaction caused by immersion in cold water rarely extended much above the ankles, whereas in these cases it rose nearly to the knees. The edema subsided promptly on bed rest, elevation of the legs and an adequate diet. The most incapacitating symptom was the neuritic pain in the feet. These persisted for nearly two months in the 3 Negroes, 2 of whom were not given special vitamin therapy. Whether due to specific action or merely coincidentally, the neuritic manifestations disappeared within a period of three to ten days in the other men after a high intake of vitamin B.

In evaluating these survivors of exposure, malnutrition and dehydration, it seems reasonable to conclude that the men of lifeboat A suffered injury from cold of slight but definite degree. This, however, falls far short of explaining the entire clinical picture that they presented. Although the crew members of lifeboat B were generally

chilled by the cloudy, heavy weather of the first five days, thereafter they suffered from intense heat and their feet remained dry except when they wet them for relief. Their most striking symptoms—edema to the knees, sensory disturbances, which in some cases involved the hands as well as the feet, stomatitis and ulceration of the gastrointestinal tract—must be accounted for on a basis other than immersion in cold water. These conditions made their appearance slowly, the first tingling and pain developing at the end of a week. The edema can be readily explained by the prolonged dependency and protein deficiency. Whether the sensory disturbances and ulceration of the mucous membranes of the digestive tract are wholly or merely in part due to vitamin deficiency must require final proof from future more complete studies. Opportunities for such studies are now frequently present, particularly in the war in the South Pacific.

In the matter of treatment, much can be accomplished prophylactically by furnishing a more suitable lifeboat ration for vessels on tropical voyages. One of the hard facts brought out by the present naval war is that dry, concentrated foods are worse than none at all when water is scarce. Although the problem of supplying a more satisfactory ration remains to be worked out, an adequate intake of the various components of the vitamin B complex can be supplied very simply and inexpensively by tablets of brewer's yeast.* The protective properties of fresh meat are well known, and whenever this can be obtained in the form of birds, fish or shellfish, the raw meat, blood, liver and other viscera can, with few exceptions,⁴ be consumed with safety. It is of interest in this connection that Captain Bligh's company, in the famous voyage from Tofoa to Timor after they were cast adrift by the mutineers on the *Bounty*, did not develop any symptoms of neuritis after six weeks on starvation rations supplemented by small quantities of fish, mussels and eggs of sea birds.⁵ Judging from the experience of Dixon, Pastula and Aldrich,⁶ who navigated the South Pacific for thirty-four days in a small rubber raft, an adequate diet can be obtained in many parts of the tropical seas if the lifeboat or raft is equipped with a small-caliber shotgun of rustless steel and a hand line or two. Richards and Bani-gan,⁴ the authors of a very practical manual on how to abandon ship, point out that a fish spear is more useful than a hook and line—"Your hook either will be taken by a large fish, which will

snap your line, or a small fish, which will be devoured before you can draw it in."

The skin can be protected against salt-water blisters in the tropics and also against cold by greasing¹; therefore a liberal supply of heavy oil should be included in all lifeboat stores. In intense sunshine the skin must also be protected by some form of clothing and, if possible, by rigging an awning over the boat. Any constricting clothing about the legs or tight shoes should be removed. In addition to greasing the feet, stretching the legs out horizontally and forcibly flexing and extending the toes are of great value in reducing edema and stiffness of the muscles. Weather and absence of sharks and barracuda permitting, getting into the water and paddling alongside the boat has been found extremely helpful by all the sailors who have tried it. This not only prevents loss of water by sweating, but the muscular movements in a horizontal position increase the flow of lymph and return a considerable quantity of edema fluid to the circulation.⁷

When survivors are picked up they should be lifted on board the rescuing vessel and carried below to prevent further damage to the skin of their insensitive, swollen feet. If there is injury to the skin from sun and salt-water burns, prevention of sepsis is important. This and the care of cold-water injuries have been described in the first part of this paper.¹ Further local treatment should include elevation of the swollen legs, Buerger's postural exercises and physiotherapy, if carried out in a hospital by an experienced person.

The most urgent need of these survivors at the time of rescue is the proper treatment of their dehydration and malnutrition. This treatment is carried out along standard lines and will not be discussed here. In addition to a high protein intake, such patients should be given a therapeutic test of vitamin B in large amounts, with daily intramuscular injections of thiamin chloride, 50 mg., and Lederle's vitamin B complex, 10 cc. (this contains thiamin, nicotinic acid and riboflavin). If the response is favorable, it will go far to establish the diagnosis of vitamin B deficiency. Once this point has been settled, a less expensive therapy consisting of brewer's yeast (which contains large amounts of all the vitamin B components) and a diet of green vegetables, carrots, butter and liver can be substituted.

SUMMARY AND CONCLUSIONS

The painful swelling of the feet observed in two lifeboat crews, adrift for prolonged periods in the Gulf Stream, had fundamental clinical and etiologic differences from the "immersion-foot" syn-

*More concentrated preparations are available that contain reasonable proportions of the various components in the vitamin B complex. Among these are Unicaps (Upjohn) and Vitamin B Complex Capsules (Lederle).

intercellular and extracellular edema in the epidermis.¹¹ The blood vessels in the corium are increased in number and are dilated, but little cellular infiltration is present and there is no endovasculitis or perivascular infiltration. Slight edema is present, as well as dissociation of the connective-tissue fibers of the corium.

Through the work of many investigators, it has now been shown that this disease in rats is due to the existence in the egg white of a substance that binds the biotin in the diet, preventing its absorption.² The specific constituent responsible for this effect has now been concentrated and purified.^{12, 13} It is a proteinlike substance called "avidin" (an abbreviation for avidalbumin, meaning "hungry albumin"). This concentrated preparation can replace raw egg white as the toxic factor necessary for the production of egg-white disease, but it must be given orally, since with parenteral administration it actually has a curative action.¹⁴ The latter phenomenon is presumably due to the fact that concentrates of avidin consistently contain some biotin, which is liberated in vivo. The only source of avidin thus far known is egg white.

The avidin-biotin compound under the conditions of the intestinal medium is a stable one and is excreted in the feces as such,¹⁵ but may be broken up by steaming or by acid hydrolysis. Avidin loses its toxic effect if the egg white is heated at 100°C. for three to thirty minutes.^{2, 16}

Animals with egg-white disease recover rapidly when placed on a normal diet and when the ingestion of egg white is stopped. They also recover even when continued on the same diet provided that adequate quantities of vitamin H (biotin) are administered. The latter is from three to five times more effective when given parenterally than when given orally.¹⁷

The identification of vitamin H¹⁸⁻²⁰ (the curative factor of egg-white disease in rats) as biotin²¹ (a growth factor for yeast) and as coenzyme R²² (a growth and respiration factor for many strains of legume-nodule bacteria) has eliminated the necessity of animal assay for the estimation of biotin and has allowed substitution for it of a simpler and quicker microbiologic method. When yeast is used as the test organism,²³ the bioassay can be performed in less than twenty-four hours.

Although biotin is widely distributed in the various articles of diet, it is found in the greatest concentrations in liver, kidney, yeast, cow's milk and pancreas.²⁴⁻²⁶ It is present in egg yolk in a high-molecular, undialyzable form, which is physiologically active in yeast-growth tests or in tests made on rats with egg-white disease.²⁷ A whole egg, however, contains a distinctly greater amount

of avidin than can be neutralized by the biotin of the whole yolk.²⁷

Biotin is insoluble in water in its natural state as it occurs in liver, kidney or yeast.²⁴ For the complete extraction of biotin, commonly present in bound form in foodstuffs and similar products, acid hydrolysis is, in general, the most suitable procedure.^{23, 26, 28-30}

Biotin was first obtained in crystalline form in 1936 in Kögl's laboratory from egg yolk.²¹ The empirical formula was reported in 1938.³ Du Vigneaud and his collaborators^{20, 31} have isolated biotin from the liver as the pure crystalline methyl ester, the physical and chemical properties of which are in close agreement with the empirical formula $C_{11}H_{18}O_3N_2S$. Their later studies^{32, 33} led to the recognition of certain functional groups of biotin, permitting them to conclude that it is a carboxylic acid containing an N, N'-substituted cyclic urea grouping and possessing sulfur in a thio-ether linkage.

CASE REPORT

R. M. (No. 1042432), a 66-year-old retired Italian laborer, was admitted to the Boston City Hospital on October 8, 1941, complaining of a chill, fever and cough. The routine clinical analyses revealed that he had a urinary-tract infection, chronic bronchitis, emphysema, arteriosclerotic heart disease (with mild congestive failure), amputated penis and exfoliative dermatitis—the last being of particular interest so far as this paper is concerned. There was no history of medication or of exposure to chemical agents to account for the rash. His dietary history was, however, significant.

Since adolescence the patient had been extremely fond of raw eggs, putting one or two into each glass of wine that he took. For several decades he had drunk wine or whiskey almost every day. During the six years preceding admission he had drunk from 1 to 4 quarts of wine daily. In order to have a sufficient number of eggs for his drinks, he deserted his family and moved to the country so that he could maintain his own chicken farm. During this period of time he ate from two to six dozen raw eggs per week. He did not eat at any regular time. Sometimes he ate only one or two meals a day, and sometimes he drank nothing but wine and eggs for 1 or 2 days. His choice of foods was narrow and consisted chiefly of canned goods; rarely did he drink milk or eat liver (sources of biotin).

So long as he could remember, his skin had been quite red, but 5 years previously the redness increased and many scales were noted. A mild conjunctivitis had been present for several months. These changes persisted, and 3 months before admission there was an increase in their severity. There was not much fluctuation in the nature of the rash. There was never any itching, vesicles, bullas or evidence of skin infection; nor was there diarrhea, sore tongue, neuralgia, cheilosis, night blindness or hemorrhagic phenomena.

In March, 1941, the patient had a partial amputation of the penis because of a carcinoma. Owing to a recurrence of the neoplasm, a more radical amputation was

performed in September, 1941. On October 8, he had a chill and fever and was readmitted to the hospital.

On examining the skin, about half the total surface (chiefly the trunk) appeared normal, but the entire face, ears, shoulders, dorsum of forearms, hands and lower legs were fiery red and covered with many medium sized

keratinization; masses of keratinized material are separated from the underlying epidermis and there is slight parakeratinization. Intracellular and extracellular edema in the stratum mucosum is present.

The corium is thickened, owing to interstitial edema and hypertrophy of the collagen fibers. The fibers

FIGURE 1 Section of Skin.

Note the loose sheet of keratinized epithelium, the absence of rete pegs and the cellular infiltration around the hair follicles, sweat glands and blood vessels.

scales. The involved areas were sharply demarcated from the normal skin. On the trunk the lesions were small and scantily scattered. There was no elevation of the skin, no raw surfaces and little if any edema. There was slight palpebral edema and moderate conjunctival injection, but no corneal vascularization. The tongue was grayish red, but there was no papillary atrophy.

The urine showed a + test for albumin, and the sediment contained many white cells, occasional red cells and no casts. Cultures of the urine repeatedly grew colon bacilli, enterococci, *Staphylococcus aureus* and occasionally *Proteus vulgaris*. The hemoglobin was 78 per cent. The white-cell count was 17,000, with 91 per cent polymorphonuclear leukocytes, 5 per cent lymphocytes and 4 per cent monocytes. A blood Hinton test was negative.

A biopsy of the skin was taken on October 10. The sections were studied by Drs. Frederic Parker, Jr., Howard T. Karsner, William R. Hill and several other pathologists. A specific diagnosis was not made, but a summary of the observations is as follows:

There is a sharp distinction between the corium and epidermis (Fig. 1). The rete pegs are flattened and in some areas they do not extend downward into the corium, leaving a flat line between the two layers. Some of the hair follicles and sweat ducts are plugged. The epidermis is of normal width but there is hyper-

keratinization; masses of keratinized material are separated from the underlying epidermis and there is slight parakeratinization. Intracellular and extracellular edema in the stratum mucosum is present. The corium is thickened, owing to interstitial edema and hypertrophy of the collagen fibers. The fibers adjacent to the epidermis are homogeneous and pale; the middle and deep fibers are thickened, but otherwise normal. The sebaceous glands are absent, the hair follicles atrophic, the arrectores pilorum muscles hypertrophic, and the sweat glands and ducts dilated. A few acini of the sweat glands are necrotic. The elastic-tissue fibers are absent in the papillary bodies and decreased throughout the cutis, except in a band in the region of the superficial capillaries, where they are increased in number and the individual fibers hypertrophic. In the deep cutis they are hypertrophic but few in number. The subcutaneous fat and nerves are normal. In the upper corium are numerous areas of cellular infiltration, involving particularly the sweat glands and the blood vessels (Fig. 2). The cells are chiefly polymorphonuclear leukocytes and lymphocytes, with a few plasma cells. The vasculitis involves chiefly the superficial vessels, since the deeper vessels of the corium are normal. The vessels in the upper cutis are increased in number and show endothelial proliferation.

The significance of these histologic findings is discussed below; it is obvious that they are not those of pellagra.

A clinical diagnosis of possible biotin deficiency was entertained, but immediate attention was given to the urinary tract infection. Nevertheless, in spite of intensive

treatment with sulfathiazole, sulfanilamide and sulfapyridine, it did not clear up during the period of observation. On admission, the patient was placed on a regular hospital diet. Five days later this was supplemented daily

of avidin in raw egg whites. Therefore, on October 22 the patient was placed on a daily diet consisting of 1500 cc. of wine, the whites of twelve raw eggs, 1½ pounds of rare steak and coffee without cream or

FIGURE 2. *Section of Skin.*
This shows the marked cellular reaction around the small blood vessels in the corium.

with 600 cc. of wine and three raw eggs. The quantities of these were increased until, a week after admission, he was eating, in addition to the hospital diet, six raw eggs daily in a quart of wine. Nevertheless, the rash

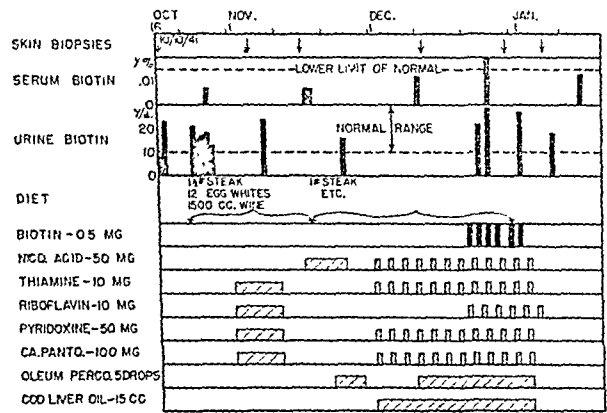

FIGURE 3. *Treatment Given the Patient and His Course in the Hospital.*

improved rapidly and by the end of 2 weeks there were only traces of it. Treatment of localized areas of the skin with ultraviolet and infrared light caused no exacerbation in the dermatitis. An attempt was then made to cause an exacerbation by limiting the biotin intake and giving a large quantity

sugar. All the wine issued had been made by the patient and contained 0.55 gamma of biotin per 100 cc. Therefore the daily intake of biotin in the form of wine amounted to approximately 8 gamma. Assays of the beef muscle were not performed.* The whites of twelve eggs contain a sufficient quantity of avidin to bind approximately 230 gamma of biotin.²⁷ Therefore, it seems that little if any biotin would be absorbed from the gastrointestinal tract. On some days, indicated in Figure 3, the diet was supplemented with 10 mg. each of thiamin chloride and riboflavin,† 50 mg. each of nicotinic acid and pyridoxine,† 100 mg. of calcium pantothenate,† 5 drops of oleum percomorphum and 15 cc. of cod-liver oil. On November 16, the steak was reduced to 1 pound per day and the regimen continued until December 29, a total of 10 weeks. On December 20, the patient was given subcutaneously 0.5 mg. of the methyl ester of biotin.† This dose was repeated on alternate days until a total of six injections had been given. During the course of this treatment the biotin level of the serum was found to be normal for the first time. The amount of biotin excreted in the urine increased, but remained within normal limits.

*Rat muscle has been found to contain some biotin,^{23, 28} although small in quantity as compared with that in liver and yeast. Beef muscle in daily doses up to 7.5 gm. has been found not to cure egg-white disease in rats.²⁴ Indeed, in some cases it seemed actually to accentuate the disease.
†I am indebted to the Winthrop Chemical Company, Incorporated, New York City, for the supply of riboflavin (Flavaxin Niphanoid); to Merck and Company, Incorporated, Rahway, New Jersey, for the supply of pyridoxine (Hexabione) and calcium pantothenate; and to the S. M. A. Corporation, Chagrin Falls, Ohio, for the supply of the methyl ester of biotin.

The second biopsy of the skin, obtained on November 4, showed marked regression of the inflammatory reaction. The subsequent four biopsies at scattered intervals during the next 2 months were essentially alike, showing to a slight degree hyperkeratosis, atrophy of the epidermis, increased pigmentation of the basal cells, edema of the corium, perivascular infiltration with lymphocytes, prominence of arrectores pilorum muscles and absence of sebaceous glands. During this time, however, there were slight or no gross abnormalities of the skin.

During the hospital stay there was a loss of 10 pounds in weight, due partially to improvement in the congestive heart failure. During this period of observation, one of the left inguinal nodes became enlarged and quite firm. This was apparently due to neoplastic extension. During the period of hospitalization the patient's general state of health appeared good and no new manifestations of vitamin deficiency developed.

DISCUSSION

The presence of an exfoliative dermatitis of several years' duration in a patient with poor dietary habits and the absence of a history of exposure to toxic factors strongly suggest that the dermatitis was due to a nutritional deficiency. A deficiency in any one of the following five vitamins has been found to induce in animals the development of a scaly dermatitis: nicotinic acid, riboflavin, pantothenic acid, pyridoxin and biotin. Therefore, the clinical and histologic changes of these vitamin deficiencies must be considered in comparison with those listed in the patient above. It should be emphasized, however, that comparisons of changes in animals may not be applicable to human beings.

A nicotinic acid deficiency can readily be eliminated, since the dermatitis was more central than peripheral and the histologic changes were definitely not those of pellagra. Furthermore, there was no accentuation of the rash on treating the skin with large doses of ultraviolet light and there was no diarrhea, delirium, atrophy of the lingual papillae and so forth.

The skin changes of riboflavin deficiency, as described in rats, are milder than those observed in this case. They usually consist of small, whitish-yellow, dandruff-like flakes or scales; the formation of large scales and exfoliation is conspicuously absent.³⁴ Histologic studies show mild hyperkeratosis, only very slight exudation in the upper corium, a decrease in the follicles and increased activity of the sebaceous glands.¹¹ In this case there was a marked exudative reaction in the corium and disappearance of the sebaceous glands. Moreover, cheilosis and vascularization of the cornea were absent.³⁵

The histologic manifestations of pantothenic acid and pyridoxin deficiencies in animals tend to overlap. With the former, there is a scaly dermatosis and alopecia without acrodynia.³ There

is also graying of the hair, hemorrhagic necrosis, serous exudate around the eyes, a twitch or paralysis of the hind legs and myelin degeneration of the sciatic nerves and spinal cord. Histologic changes of the skin in pantothenic acid deficiency have not been clearly distinguished from those due to pyridoxine deficiency.

Animals deficient in pyridoxine have a scaly dermatosis that is most marked around the nose, mouth and distal ends of the extremities.³⁶ Some areas of the skin remain normal. The formation of abscesses is common. On histologic examination one notes marked hyperkeratosis, acanthosis and intercellular edema of the epidermis.^{11, 36, 37} The corium is also edematous and hyperemic and is diffusely infiltrated with lymphocytes, large mononuclear cells and, later in the disease, polymorphonuclear leukocytes. In the early stages the hair follicles and sebaceous glands remain intact, but in the late stages there is an infiltration of polymorphonuclear leukocytes into and around the hair follicles and sebaceous glands.

In animals with disease due to egg-white injury, there is acanthosis, parakeratosis, hyperkeratosis and intracellular and intercellular edema, without much cellular infiltration.³⁴

The changes that were noted in the sections of the skin of this patient were not entirely like any of the above-mentioned vitamin deficiencies. The picture was somewhat like that of biotin deficiency, but in addition there was a marked cellular reaction. The latter suggests the possibility of a pyridoxine deficiency, either alone or combined with biotin deficiency. The clinical picture, however, was not similar to the acrodynia of rats.

Thus, in summary, one may state that the macroscopic and microscopic changes of the skin of the patient were compatible with the diagnosis of biotin deficiency, but not pathognomonic of the condition as seen in animals.

Assays of the serum revealed that the biotin content was below the normal level. The first urine specimen was also low, but all subsequent ones were within normal limits (Fig. 3).

The ward diet during the first two weeks of hospitalization was perhaps sufficient in biotin content to account for the almost total disappearance of the rash. In spite of the fact that the patient was then placed on a dietary regimen permitting little or no absorption of biotin from the gastrointestinal tract, there was no exacerbation of the rash and the urinary excretion of biotin remained normal. The biotin content of the serum, however, stayed below normal. It seems that this apparently paradoxical situation can best be attributed to the persistence of the urinary-tract infection. It has been shown that many bacteria can

synthesize biotin. The colon bacillus and *Staph. aureus* can produce it in large quantities,³⁸ and these organisms were repeatedly present in the urine of the patient, although he had been treated with various sulfonamides. It is probable that some of the biotin synthesized in the kidneys was absorbed by the vascular system and distributed throughout the body.

Large doses of various members of the vitamin B complex, including biotin, did not cause complete disappearance of all the histologic changes in the skin.

If this case is correctly interpreted as one of biotin deficiency, it is of interest that the patient developed a carcinoma of the penis with progressive growth while in a state of biotin deficiency, because du Vigneaud et al.³⁹ have found that rats rendered biotin-deficient rarely develop carcinomas when fed butter yellow. Biotin was, however, regarded by them as exerting a procarcinogenic effect when butter yellow was fed to rats receiving a highly protective diet.

SUMMARY

A patient with an exfoliative dermatitis of several years' duration has been described. A long history of the ingestion of large quantities of raw eggs and of poor dietary regulation suggests that he had biotin deficiency.

Assays for biotin revealed that its content in the serum was persistently below normal, although it returned to normal on treatment with biotin. Most of the urine values were normal, possibly because of the persistence of a urinary-tract infection with biotin-producing organisms.

The dermatitis largely disappeared after the patient had been on a regular ward diet, without many raw eggs, for a period of two weeks.

Attempts to induce the reappearance of the dermatitis by the administration of a diet with large quantities of raw egg white and of low biotin content failed, possibly owing to the infection of the urinary tract.

The coexistence of a carcinoma is of interest in a patient with possible biotin deficiency.

I am indebted to Dr. Paul György, of the Babies' and Children's Hospital, Cleveland, Ohio, for his numerous helpful suggestions and the bioassays of the various specimens for biotin.

MEDICAL PROGRESS

ENDOSCOPY*

EDWARD B. BENEDICT, M.D.†

BOSTON

ENDOSCOPIC procedures are being used more and more frequently in all large clinics, where facilities for them are readily available. The clinician must know when to call on the specialist for the various endoscopies. It is hoped that the following review will help to indicate the trend of modern endoscopic thought and will assist the physician in deciding when the endoscopist should be called in consultation.

ANESTHESIA

In all the large endoscopic clinics local anesthesia is used almost entirely. In the clinic at the Massachusetts General Hospital 5 per cent Larocaine Hydrochloride or 2 per cent Pontocaine Hydrochloride has been substituted for cocaine, because although the latter may be somewhat more effective, it is probably more toxic than either Larocaine or Pontocaine. During the last few months it has been impossible to obtain Larocaine, and 2 per cent Pontocaine has been used entirely, without untoward results.

A reaction to Pontocaine, however, was reported by Phillips, Congleton and Tuttle.¹ Approximately 5 cc. of 0.5 and 1.0 per cent Pontocaine was used. Almost immediately there were fainting, twitching of the facial muscles and general tonic contractions, which were relieved by the intravenous administration of Dial. Other reactions to Pontocaine have been reported, but none to Larocaine.

BRONCHOSCOPY

Bronchiectasis. Blades and Graham² in a discussion of the surgical treatment of bilateral bronchiectasis mention that in some cases there has been difficulty in deciding from the appearance of lipiodol bronchograms which of the lungs was more extensively diseased. In these cases the impressions gained by bronchoscopic examinations were relied on to determine the major source of pus.

Diamond and Van Loon³ studied 75 cases of bronchiectasis in children from the point of view of bronchoscopic aspiration, and concluded that

most of the patients were subjectively improved by repeated bronchoscopies, but that in not a single case was there an anatomic cure.

Hemorrhage. In a study of 436 patients with hemoptysis, Jackson and Diamond⁴ found the commonest causes to be bronchiectasis (138 cases), carcinoma (82 cases), tracheobronchitis (74 cases), pulmonary abscess (51 cases), no evidence of disease (34 cases), nonsuppurative pneumonitis (15 cases), suppurative pneumonitis (11 cases) and adenoma (11 cases). Other rare diagnoses made up the balance of the series. The high percentage of tracheobronchitis is worthy of note, for many physicians do not seem to recognize this condition as a cause of hemoptysis. In all these cases x-ray examination of the chest was negative. Nine patients had had one or more massive hemoptyses.

Parrish⁵ reports 1 case of fatal hemoptysis in which bronchoscopy showed only a friable mucosa. This was confirmed by autopsy, which showed only erosions of the bronchial mucosa. This seems comparable to the cases of massive and even fatal hemorrhage from gastritis, and serves to emphasize the fact that serious hemorrhage does occur from badly inflamed mucous membranes with erosions but without actual ulcerations.

Asthma. Bases and Kurtin⁶ emphasize the importance of bronchoscopic aspiration in status asthmaticus. They report that 6 of the 7 patients who died of status asthmaticus at the Mount Sinai Hospital in the past fifteen years and on whom autopsies were performed died from blocking of the tracheobronchial airway by excessive outpouring of secretion. In many cases death could have been averted by bronchoscopic removal of the obstructing secretion.

Postoperative bronchoscopy. Schmidt, Mousel and Harrington⁷ stress the necessity of preventing atelectasis in the postoperative patient. In certain cases of bronchial obstruction they advise one or more bronchoscopic aspirations before operation to free the lung of as much of the infected secretion as possible.

Sealy and Priestley⁸ report a case of total gastrectomy and cholecystectomy at the same time with very smooth convalescence. They attributed this result to an immediate postoperative bron-

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual, Vol. III, 1942* (Springfield, Illinois: Charles C. Thomas Company, 1942. \$5.00).

*From the Massachusetts General Hospital.

†Instructor in surgery, Harvard Medical School, associate visiting surgeon, Massachusetts General Hospital.

choscopy during which a considerable amount of bloody debris was aspirated from both sides of the tracheobronchial tree, and believe that had this material not been aspirated, a pulmonary infection would in all likelihood have developed which would have interfered materially with the patient's convalescence. At the Massachusetts General Hospital we consider this of such significance that we are training our anesthetists in the use of the bronchoscope for postoperative aspiration of secretions.

Bird⁹ writes interestingly regarding the value of bronchoscopic aspiration immediately following operation. He reports that after the passage of an ordinary catheter through the endotracheal tube, one may still hear bizarre, coarse rales over various portions of the bronchial tree. If a bronchoscope is then introduced, exudate is always found, usually in small amounts, distributed irregularly along the sides of the trachea and large bronchi and in the orifices of some of the secondary bronchi. On removal of this bubbling fluid, on auscultation the lungs will be found entirely clear. Bird believes that removal of this residual, even though small, is essential, for if it remains it may cause localized bronchial infection and an exhausting, ineffective cough.

Carcinoma. Holleb and Angrist¹⁰ report 2 cases of bronchogenic carcinoma associated with pulmonary asbestosis. Although these cases are of interest, it is impossible to prove a causal relation between the two conditions.

Prickman, Maytum and Moersch¹¹ observed 3 cases of primary bronchogenic carcinoma in asthmatic patients. Here again the significance of chronic irritation in the development of carcinoma is of interest but no causal relation can be proved.

Ochsner and DeBakey¹² have made a careful study of metastases from primary carcinoma of the lung, and conclude that in this disease there is a high incidence of metastases at the time the diagnosis is made, although fortunately some cases of bronchogenic carcinoma are characterized by late and limited metastases. The relative incidence of metastases to various organs and lymph nodes based on a collected series of 3047 cases is presented.

Goldman¹³ made a special study of carcinoma of the lung of long duration. In a series of 11 selected cases, 10 of which were epidermoid, the duration from the time of onset of symptoms until diagnosis averaged ninety months. Goldman blames the delay in diagnosis on the inadequacy of bronchoscopy and roentgen examination to demonstrate early small peripheral tumors, particularly when complicated by empyema and abscess. *He urges the education of both patient and physi-*

cian "to produce in them an anaphylactic reaction" to the possibility of cancer in men over forty with symptoms of pulmonary disorder.

Adams, Steiner and Bloch¹⁴ discuss what they call malignant adenoma of the lung, or carcinoma-like tumors of several years' duration. They report 5 cases of endobronchial tumor characterized by a long clinical course with low-grade but definite malignant manifestations. I believe that in general it is possible for pathologists to differentiate benign from malignant tumors. The term "bronchial adenoma" should denote a benign tumor, and as a tumor becomes invasive it should be called a carcinoma. "Malignant adenoma" seems to be somewhat of a contradiction in terms.

Clerf and Bucher¹⁵ report 35 cases of adenoma of the bronchus in 243 consecutive cases of carcinoma, an incidence of 14 per cent. In one case an adenoma involved the trachea and both main bronchi. In another, an apparently benign adenoma was shown five years later to be a carcinoma; at post mortem there was a mass in the lung with metastatic carcinoma in the lymph glands of the mediastinum. When one considers the possibility of some adenomas' being relatively low-grade carcinoma, it is evident that lobectomy or pneumonectomy must be seriously considered, not only from the point of view of possible malignancy but also because, even in benign adenomas, there is frequently irreparable lung damage.

Tuberculosis. Brantigan, Hoffman and Proctor¹⁶ point out that the increasing use of bronchoscopy for tuberculous patients has revealed a significant percentage of pulmonary lesions to be complicated by endobronchial lesions. They advise routine bronchoscopies before the performance of pneumolysis.

Durkin and Vinson¹⁷ report the favorable outcome of a tuberculous bronchial stricture treated by high-voltage roentgen therapy. Since tracheobronchial tuberculosis may heal spontaneously, the value of x-ray therapy in this disease is easily exaggerated.

Phelps¹⁸ emphasizes the poor prognosis in tracheobronchial tuberculosis, having found 31 per cent of a series of patients dead in five years, 63 per cent with chronic disease and only 6 per cent completely recovered. He finds the local application of 30 per cent silver nitrate helpful.

Alexander, Sommer and Ehler¹⁹ are opposed to any form of collapse therapy for pulmonary tuberculosis when there are signs or symptoms of tracheobronchial tuberculosis until bronchoscopy has been performed to determine the type, position and extent of the bronchial lesions. After a long discussion, these authors conclude that there are certain clear-cut indications and contraindications

to both pneumonectomy and thoracoplasty in the treatment of pulmonary tuberculosis with bronchial stricture, atelectasis and fibrosis that must be strictly observed if a high percentage of therapeutic failures is to be avoided. In some cases neither pneumonectomy nor thoracoplasty can be used safely. For those cases in which no contraindication to either pneumonectomy or thoracoplasty exists, they believe that thoracoplasty is the better operation, because the mortality is much lower than with pneumonectomy and the percentage of apparent healing of the tuberculosis is much higher. Chamberlain and Gordon²⁰ consider the problem of endobronchial tuberculosis involving the large bronchi as essentially one of mechanical obstruction and its complications (emphysema, bronchiectasis, atelectasis and so forth). They also hold that early bronchoscopic recognition of the bronchial disease and reduction in the size of the pulmonary bed before chronic stenosis occurs are of fundamental importance in the therapeutic program; that pneumothorax is a dangerous form of therapy when the bronchial disease is severe and large bronchi are involved; that the local application of silver nitrate often aids therapy directed at the pulmonary lesion; and that severe endobronchial tuberculosis produces permanent damage to the bronchus and is accompanied by irreversible sequelae. *A permanent form of therapy is therefore indicated. The results from thoracoplasty have been good. External drainage, lobectomy and pneumonectomy may be used in selected cases.*

Thornton and Adams²¹ in an article on the resection of lung tissue for pulmonary tuberculosis conclude as follows: The commonest complications have been persistent fistula, contralateral spread and empyema. The commonest indications for operation have been tuberculoma and isolated tuberculous lesions simulating tumor, tuberculous bronchiectasis, bronchial stenosis and post-thoracoplasty cavities. The best results were obtained in patients with closed lesions or with negative sputums. Resection of lung tissue in cases with bronchial stenosis is suggested only if secretions cannot be made to drain past the stricture. Rarely lobectomy or pneumonectomy may be performed in this type of case in the presence of a positive sputum; in general, however, resection of lung tissue is hazardous in the presence of a positive sputum. If possible, collapse therapy is preferred.

Benedict²² in a symposium on bronchial obstruction discussed the problem of tracheobronchial tuberculosis. He emphasizes the fact that only by bronchoscopy can the differential diagnosis be established between this disease and other diseases

causing bronchial obstruction, especially benign and malignant tumors.

From this review of the literature it is apparent that the medical profession is becoming increasingly aware of the importance of bronchoscopy in tuberculosis.

ESOPHAGOSCOPY

Carcinoma. The most significant advance in surgery of the esophagus has been resection of lesions of the lower end by the transthoracic approach. Churchill and Sweet²³ have reported their experiences in this field and have described in detail the operative procedure whereby the tumor is resected and a direct anastomosis made between the esophagus and stomach. Esophagoscopy is essential for determining the nature and level of the lesion, and especially for procuring tissue for microscopic diagnosis. The results of operation compare favorably with those for resections for carcinoma in other locations of the stomach.

Carcinoma of the upper esophagus is notoriously difficult to treat, but Wookey²⁴ has described a method of surgical removal of such growths even when they involve the hypopharynx. Complete removal of the larynx and pharynx may be necessary, and in such cases it has been possible to reconstruct the pharynx and upper esophagus to permit the normal taking of food.

Benign tumors. Samson and Zelman²⁵ report that benign tumors are often asymptomatic and are encountered accidentally at autopsy. They are located predominantly in the upper fourth of the esophagus and include lipoma, myxoma and fibroma. In a series of 26 cases of grossly pedunculated tumors, 3 patients died suddenly because of regurgitation of the tumor into the larynx. After a thorough consideration of treatment by esophagotomy or esophagoscopy, it is the opinion of the authors that endoscopic removal is superior to extirpation by external esophagotomy.

Benign stricture. Certain cases of esophageal stricture have been found to be impenetrable. In such cases Drash and Woodward²⁶ recommend a surgical approach combined with the use of a bougie manipulated within the esophagus and manually from without.

Cardiospasm. Etzel²⁷ presents data which he believes tend to show that megacardiospasm (cardiospasm), megacolon, achalasia of the pylorus, megarectum and disturbances in the cardiac conduction system are but varied manifestations of the same disease. A chronic or intermittent deficiency of vitamin B₁ is suggested as the etiologic agent of the degeneration in the autonomic nervous system, thereby instituting a series of physiopathologic

changes that culminate in the clinical picture described.

Samson and Foree²⁸ have reviewed the literature on the injection treatment of esophageal varices and report 1 case in which sclerosis was obtained by nine injections of 0.5 to 6.0 cc. of 2.5 per cent sodium morrhuate. They believe that the method has merit and deserves further trial. In their case many varices were present in the stomach.

GASTROSCOPY

Taylor²⁹ has described a new gastroscope the flexible part of which can be curled up or allowed to lie flaccid. It is flexible in all directions, but can be bent forward and backward in the plane of the objective up to the limits of optical flexibility. By reason of this controllable flexibility the new instrument possesses the following advantages: greater safety of instrumentation, less likelihood of failure of instrumentation, abolition of blind areas in the stomach, ability to move the instrument about in the stomach so as to inspect any particular area closely at will and from more than one angle and greatly increased illumination with less distortion of the image. In fact, endoscopic photography, which has previously been impossible with other flexible gastroscopes, has now become practicable.

Gastritis. Barnett³⁰ studied the symptoms of superficial gastritis and found no correlation between the symptoms and the severity of the gastritis as seen through the gastroscope. He found frequent gastroscopic evidence of transition from superficial to atrophic gastritis.

Benedict³¹ in a series of 1300 cases examined by gastroscopy found hypertrophic gastritis without other gastric or duodenal disease in 117 cases (9 per cent). The commonest symptom was epigastric pain, which occurred in 74 per cent of the cases. It was relieved by food or soda in 81 per cent, related to meals in 52 per cent and present at night in 21 per cent. The similarity to ulcer pain is therefore striking. Other frequent symptoms were vomiting (45 per cent), hemorrhage (42 per cent), gas (41 per cent), sour eructations (16 per cent) and heartburn (15 per cent). Clinical improvement was in most cases definitely correlated with the improvement in the gastric mucosa as seen by gastroscopy. The expert roentgenologist using the relief technic may be helpful in suggesting a possible diagnosis of gastritis, but the only way of obtaining a positive diagnosis is by gastroscopy, and only by it can the differential diagnosis be made between the superficial, atrophic and hypertrophic forms. No method is wholly accurate in differentiating some severe cases of hypertrophic gastritis from those of carcinoma. In

doubtful cases surgical exploration, including gastrotomy and biopsy, should be performed.

Olleros³² points out that pernicious anemia is usually accompanied by atrophic gastritis, which may improve with liver therapy to a point where as observed through the gastroscope the lesion appears to be undergoing complete cure, although the improvement is never accompanied by histologic restoration. In tropical sprue Olleros found atrophic gastritis localized or generalized, but not so severe as that seen in pernicious anemia. After liver therapy the symptoms were checked and the gastroscopic characteristics ceased to predominate.

Einsel³³ reports a case of superficial ulcerative gastritis following tryparsamide therapy for syphilis. This patient had had heavy antisyphilitic treatment, which was followed by uncontrollable vomiting of several weeks' duration. Gastroscopy demonstrated hundreds of eroded areas, 2 to 4 mm. in diameter, with a pearly-white base and red edge. The mucosa was edematous and bled easily.

Judd³⁴ has carefully studied the residual lesions of ulcerative gastritis and their possible relation to the development of carcinoma of the stomach. In a review of the literature he emphasizes that cancer is always accompanied by gastritis (Faber³⁵); that cancer never develops in a healthy stomach (Hurst³⁶); that most carcinomas of the stomach probably arise on the basis of a chronic atrophic gastritis (Tuomikoski³⁷); that gastric carcinoma may follow the atrophic type of gastritis (Schindler, Ortmayer and Renshaw³⁸); and that the hyperplasia of the mucous glands may have some relation to the development of carcinoma (Robertson³⁹). Judd made a microscopic study of surgically resected stomachs, and found a consistently lower incidence and markedly less prominent degree of hyperplasia in the control groups than in the cancer group, lending support to the conclusion that hyperplasia or regenerative activity is an important factor in the pathogenesis of carcinoma of the stomach. His final conclusions are that carcinoma develops in a previously damaged stomach; that many years of such injury may be required before neoplastic transformation begins; and that the pathogenesis of gastric carcinoma is directly related to the disorganized hyperplasia of gastric mucous cells.

Benedict and Mallory⁴⁰ made a careful study of 51 cases of surgically resected stomachs in an attempt to correlate the gastroscopic with the pathological findings in gastritis. The correlation was found to be more accurate than had been expected, and confirms the accuracy of the gastroscope in the diagnosis of gastritis and the differentiation of the various types of gastritis. Superficial gastritis as described by the gastroscopist cor-

responds to the acute exudative gastritis of the pathologist. The term "atrophic gastritis" is used by both gastroscopist and pathologist to denote the same type of mucosa. Hypertrophic gastritis as described gastroscopically corresponds to an exaggerated form of the physiologic plasma-cell and lymphocytic infiltration of the normal stomach. In this series there was complete or partial agreement between the gastroscopist and the pathologist in 88 per cent of the cases.

Gastric ulcer. Wolf and Wolff⁴¹ studied the effect of emotions on the gastric mucosa of a patient with a gastric fistula, and found that intense sustained anxiety, hostility and resentment were accompanied by severe and prolonged engorgement, hypermotility and hypersecretion in the stomach. In this state mucosal erosions and hemorrhages were readily induced by even the most trifling traumas, and frequently bleeding points appeared spontaneously as a result of vigorous contractions of the stomach wall.

Carcinoma. Moersch and Weir⁴² present a case of prolapse of the gastric mucosa in which the lesion was misinterpreted gastroscopically as being gastric carcinoma. They believe that repeated gastroscopic examinations obviate such errors, and that palpation of the abdomen during gastroscopy aids the gastroscopist in determining the pliability of the gastric wall and in bringing into view portions of it that might otherwise not be visualized.

Templeton and Boyer⁴³ have analyzed the gastroscopic and roentgenologic findings in the diagnosis of gastric cancer, and conclude as follows: In most cases a gastric cancer visible by one of the two methods of examination is demonstrable by the other, and will be diagnosed correctly by both the gastroscopist and the roentgenologist. Sometimes a lesion, by virtue of its location and morphology, is visible only to the gastroscopist or to the roentgenologist. Occasionally, lesions that are demonstrable by both methods are diagnosed as malignant by one examiner and as benign by the other, and when the facts finally become known it is found that the gastroscopist is no more and no less likely than the roentgenologist to be correct. Lastly, a combination of gastroscopy and roentgenology will result in a higher percentage of correct diagnoses than will either procedure alone.

Benign tumor. Cohn, White and Weyrauch⁴⁴ report an interesting case of granuloma of the stomach which followed the ingestion of medication containing colloidal kaolin (hydrated aluminum silicate). The patient had had abdominal pain, pyrosis, nausea and vomiting for eight years. Clinical and roentgenologic examination revealed no gastric disease. Gastroscopy showed a prepyloric tumor, which, however, was not seen in the

grossly resected stomach. Microscopic study proved the lesion to be a granuloma with the type of foreign-body giant cell present in the lesions of silicosis. Mineralogic studies confirmed the presence of silica in the gastric tissues. Following resection the patient became asymptomatic and remained so for over two and a half years.

Schindler, Sandweiss and Mintz⁴⁵ state that it is possible to make a diagnosis by gastroscopy of a benign submucosal tumor by the stretching of a mucosal fold from the surrounding mucosa up to the surface of the tumor. The appearance of this type of tumor as seen by gastroscopy has also been illustrated by Benedict.⁴⁶

Seasickness. Schwab⁴⁷ studied 38 cases of chronic seasickness in naval personnel and found that the patients fell into two groups: those constitutionally sick, with a history of car, bus and other sickness and with poor efficiency at sea; and those with severe seasickness, without the history of other sicknesses ashore and with a fair degree of efficiency at sea. Unfortunately, gastroscopy was carried out in only 2 cases.

PERITONEOSCOPY

Beling⁴⁸ believes that peritoneoscopy has not received the attention to which it is entitled. He thinks that if its indications and contraindications were better understood, the correct use of the peritoneoscope would bring about more accuracy in diagnosis and more correct treatment. He states that peritoneoscopy is indicated for the following conditions: noninflammatory disease of any of the organs within the greater sac of the peritoneal cavity, excluding the contents and border of the lesser sac, the pancreas, the kidneys and other retroperitoneal structures, with certain exceptions; a pancreatic growth, particularly one interfering with the continuity of the common bile duct, or one suspected of metastasis; a retroperitoneal mass (for determination of the location of an intra-abdominal mass with relation to the peritoneum); a suspected neoplasm or anomaly of any of the pelvic organs, including endometriosis; old chronic inflammatory disease of any of the pelvic organs; suspected ectopic pregnancy; splenomegaly or hepatomegaly; ascites not of cardiac origin; and tuberculous peritonitis. He particularly emphasizes the importance of peritoneoscopy in determining the presence or absence of liver metastases, primary carcinoma of the liver, hepatic cirrhosis, pelvic malignancy and ascites.

Donaldson, Sanderlin and Harrell⁴⁹ report a method of suspending the uterus without open abdominal incision by using the peritoneoscope and a special needle. This appears to be an ingenious idea, and the procedure is no doubt prac-

licable in certain cases, but I am advised by gynecologists in this clinic that this type of suspension (Olshausen) is seldom used nowadays, and that therefore peritoneoscopic suspension would be infrequently indicated.

Hamilton⁵⁰ reports a new instrument consisting of a blunt-tipped rod with a "manipulator" and an insulated endothermy electrode, both of which fit into the sheath of a small paracentesis trocar through an airtight nipple. When needed, the trocar and sheath are introduced through a tiny separate stab wound under peritoneoscopic view, the trocar is removed, and the manipulating rod or electrode is inserted. The electrode is capable of dividing adhesions, opening benign cysts and so forth. With the rod, obstructions to peritoneoscopic vision are pushed aside or hidden structures are lifted into view. The author reports no accidents, and gratifying results.

**CASE RECORDS OF THE
MASSACHUSETTS GENERAL HOSPITAL**

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29081**PRESENTATION OF CASE**

A four-month-old girl was sent to the hospital because of fever, cough and extreme restlessness.

Three days prior to admission the patient developed a slight dry, hacking cough and seemed pale. She moaned all night, seemed feverish and became increasingly irritable. Her appetite was poor, but she took water well. At no time did she vomit. Bowel movements were normal. The child was treated at home with *Argyrol* nose drops and alcohol rubs.

The family history was negative. There was no evident exposure to contagion or illness of any kind. The child was delivered at term after a normal pregnancy. She was breast fed, and vitamin supplements were provided after three weeks of age. The child gained weight and seemed quite normal prior to the present illness.

Physical examination disclosed a well-developed and well-nourished but acutely ill child who was flushed but seemed well hydrated. Respirations were rapid and of a grunting type. There was no rash. The fontanelles were flat. Both eardrums were slightly congested, but the landmarks were normal. The nose was clean. The throat was slightly congested. Expansion of the chest was symmetrical. Over the entire lower part of the left lung the percussion note was impaired and bronchovesicular breathing was audible. Examination of the heart and abdomen was negative. The liver edge was palpable at the costal margin.

The temperature was 104°F.

Examination of the blood revealed a red-cell count of 4,200,000 with a hemoglobin of 105 per cent, and a white-cell count of 15,450 with 53 per cent polymorphonuclear leukocytes, 38 per cent lymphocytes and 9 per cent monocytes. A throat culture demonstrated a few beta-hemolytic streptococci.

An x-ray film of the chest showed an area of consolidation behind the heart in the left lower lobe. The left costophrenic angle was partially obliterated.

In spite of a course of sulfadiazine producing a blood level of 5.0 mg. per 100 cc. the child's tem-

perature remained elevated, spiking daily to over 104°F. On the second day after admission the right eardrum was acutely inflamed and bulging and the landmarks were obliterated. One observer believed that the signs of consolidation had spread to the left upper lobe and possibly to the right upper lobe. Marked abdominal distention developed, and the child died on the fourth day after admission, the temperature finally rising to 106.1°F and the respirations to 60.

DIFFERENTIAL DIAGNOSIS

DR. RALPH A. ROSS: The history in this patient is one of a mild respiratory infection gradually progressing without apparent fluctuation. The remark about the moaning of the child is of some interest since babies who are sick often have a sighing type of respiration that might be called moaning.

The examination at the time of admission gave evidence of bilateral otitis media shown by congestion of both eardrums and also of some type of consolidation in the left lower lobe. The red-cell count was normal. One wonders whether the hemoglobin reading of 105 per cent was accurate. It is a striking degree of hyperchromatism in the red cells for an infant of four months; in the newborn period, of course, it is regularly seen. The leukocytosis is perfectly compatible with an acute infection in a child of this age. The relatively high percentage of monocytes does not point in any one direction.

The most important laboratory finding is the throat swab; even a few colonies of beta-hemolytic streptococcus in an infant of four months are of possible pathologic significance. However, it is generally understood that throat cultures are not indicative of the true etiologic agent in the lower respiratory tract; one should make a nasopharyngeal culture or one from material coughed up from the lower respiratory tract. To obtain the latter is a difficult procedure, which takes some degree of experience. The former can be easily carried out with the proper equipment. One wonders about blood cultures. There is no mention of them.

I should like to see the x-ray films.

DR. GEORGE W. HOLMES: The process spoken of in the chest is visible at this point, close to the angle of the diaphragm and the spine, and is more or less hidden by the shadow of the heart. There is also an area out toward the periphery that obscures the angle between the diaphragm and the chest wall, which may be a continuation of the same process. The diaphragm is not elevated. There is no evidence of decreased aeration in the lung. One would not seriously consider a plug-

ging of the bronchus, with a collapsed lung. It looks more like consolidation of some sort.

DR. ROSS: There is no evidence of fluid?

DR. HOLMES: No.

DR. ROSS: The clinical picture, together with the laboratory evidence, is one of a generalized respiratory infection involving the throat and ears and producing a localized pneumonic process. One is tempted to incriminate the hemolytic streptococcus as the etiologic agent, inasmuch as that organism was found in the throat. However, hemolytic streptococci may be found at the same time that other pathogenic organisms are present in the lower or upper respiratory tract and may not be the real cause of the difficulty. In this age group, under six months, pneumonia is still a serious problem. Before the advent of chemotherapy the fatality rates in this age group were as high as those at the other extreme of life. Some figures show up to 40 or 50 per cent mortality.

Thus we have a patient who was, by reason of her age, unable to handle the type of infection that we suppose was present. Lack of adequate response of the patient to infection often leads to the accumulation of purulent material, either because of infection of the serous cavities or because of a breaking down of the involved portion of the respiratory tract.

In the hospital course there was a steady progression downhill, with a spiking temperature and the probable spread of the pneumonia. The question of fluid in the pleural cavity comes to mind as the cause of spread of signs in the chest, but we have no further evidence of that. The appearance of otitis media of a purulent type indicates a progression of the process. One wonders whether we are justified in saying it was justifiable to state that the temperature remained elevated "in spite of a course of sulfadiazine producing a blood level of 5 mg. per 100 cc." Five milligrams is considered the lower limit of the effective level of sulfadiazine, and, particularly in this age group, a higher level should be aimed at. The development of distention in the last forty-eight hours of life may have been entirely on the basis of paralytic ileus, which is frequently seen in serious pneumonia. On the other hand it may have been due to the spread of the infection to the peritoneum.

The diagnoses are localized pneumonia, purulent otitis media on the right and a purulent intrathoracic complication — empyema or a breakdown of the involved lung into multiple abscesses. Peritonitis is a remote possibility.

DR. ALLAN M. BUTLER: Another point that this case brings to mind is the necessity today of trying to be specific in the bacterial diagnosis of a severe respiratory infection, whether it is tracheitis,

bronchitis or pneumonia. One wonders if all of us at times have been a little too satisfied with just giving sulfonamide therapy in such cases without tracking down the specific etiologic agent. The reason it is important is that we have specific therapy for certain types of infection. For instance, with influenzal infection we have specific anti-influenzal rabbit serum that should be given in conjunction with chemotherapy. If Dr. Castleman should say in a moment that the cause of infection in this child was a staphylococcus and not a beta-hemolytic streptococcus, then, with penicillin available, the specific therapy should be a combination of penicillin and sulfadiazine. The search for the specific infectious agent should be pursued with just as much intensity now as it was prior to the days of sulfonamide therapy.

DR. BENJAMIN CASTLEMAN: How would you go about it?

DR. BUTLER: In this particular case, every effort should have been made to get nasopharyngeal cultures, which are better than throat cultures. With the spike in temperature, blood cultures should have been obtained. I imagine such efforts were made but were not successful.

DR. CASTLEMAN: A blood culture was taken but did not grow out by the time the patient died.

CLINICAL DIAGNOSES

Bronchopneumonia.
Bilateral otitis media.

DR. ROSS'S DIAGNOSES

Pneumonia, localized.
Otitis media, purulent, right.
Intrathoracic purulent complication (empyema or multiple abscesses).

ANATOMICAL DIAGNOSES

Pulmonary abscesses, multiple, left.
Empyema, left.
Bronchopneumonia, left.
Otitis media, acute, bilateral.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The autopsy on this child showed an empyema in the left pleural cavity, which was filled with thick creamy-yellow purulent material. The visceral pleura of that lung was studded with small abscesses 1 or 2 mm. in diameter. A cross section of the lung showed that the parenchyma itself was diffusely involved with abscesses 2 or 3 mm. in diameter. The intervening lung tissue was consolidated. The process probably began as a pneumonia and then rapidly broke down into small abscesses. A culture of the middle ears, both of which contained pus,

showed *Staphylococcus aureus*. I think therefore that we can be quite certain that the whole process was due to a staphylococcal infection, although the blood culture, even after a period of two weeks, showed no growth.

DR CHARLES JANEWAY: Was there a culture from the empyema cavity?

DR CASTLEMAN: One was taken but we could not find the report, I am sure that it was due to a staphylococcus. The fluid was thick and purulent, not the type one sees with a hemolytic streptococcus. There was no evidence of infection anywhere else including the sinuses of the head.

DR HOLMES: What was the date of death?

DR CASTLEMAN: Four days after the films were taken.

DR HOLMES: Do you think it would be possible for empyema to develop after these films were taken?

DR CASTLEMAN: Yes. There probably was some pleurisy at the time the films were taken, but probably little if any fluid.

DR JANEWAY: I should like to emphasize the fact that this was a staphylococcal case and that bacteriology of the respiratory tract should not be done in the conventional way, particularly when dealing with infants or children. Our tendency is to type a sputum for pneumococci and not even culture it. We are gradually getting away from that, but bacteriologists are prone to look at a plate only for hemolytic streptococcus and pneumococcus. If they do not see them they say that there are no important organisms. In the influenza epidemic two years ago, when staphylococcal pneumonia was a complication, we missed one or two cases until we became aware of the fact that on the blood plate made from the sputum the staphylococcus was by far the predominant organism. That is true in any severe infection of the respiratory tract in an adult when there is a virus infection or when there is trauma, such as occurs from the inhalation of smoke or poison gases, both of which give the way for secondary bacterial invasion. In the infant susceptibility is so great that no antecedent damage is necessary to enable the less pathogenic microorganisms to invade the lungs.

CASE 29082

PRESENTATION OF CASE

A sixty-two year-old blind housewife was sent to the hospital because of pain in the right foot.

Five years prior to admission the patient was said to have dropped a flatiron on her right foot. Three months before entry she noticed a constant

dull nonradiating pain in the lateral aspect of the foot, which became progressively worse. Approximately a month later swelling developed over the dorsolateral aspect of this foot, particularly after standing.

Her husband and a daughter were living and well. Sixteen years before admission the patient was treated for a gonococcal ophthalmia that produced bilateral corneal opacities and blindness. She denied venereal disease. For several years the patient had suffered from a loose cough, which was never productive of sputum. At no time had she had fever, chills, night sweats or hemoptysis.

Physical examination disclosed an obese woman in no distress who looked older than her stated years. Both corners were opaque. Medium coarse rales were audible posteriorly at the bases of both lungs. Examination of the heart and abdomen was negative. There was a firm, tender swelling of the right foot in the region of the fifth metatarsal bone. The mass could not be moved, did not pulsate and seemed to be attached to the underlying structures. The skin over the involved area was not red or edematous.

The blood pressure was 160 systolic, 85 diastolic. The temperature was 98.6°F, pulse 71, and the respirations 24.

The examination of the blood revealed a red cell count of 4,490,000 with a hemoglobin of 75 per cent, and a white cell count of 9000, with 33 per cent polymorphonuclear leukocytes, 20 per cent large lymphocytes, 33 per cent small lymphocytes, 10 per cent monocytes, 2 per cent basophils, 1 per cent eosinophils and 1 per cent unclassified cells. There was a moderate achromia of the red cells, and the platelets were slightly reduced. The urine was acid in reaction, had a specific gravity of 1.014 and showed a ++ test for albumin; the sediment contained 7 red cells, 50 white cells and 4 epithelial cells per high power field. The blood Hinton test was negative. The tuberculin test, employing a 1:1000 dilution of OT, was markedly positive.

An x-ray film of the right foot was unusual. The medial two thirds of the shaft of the fifth metatarsal bone showed osteophyte formation and short spicules of calcification extending laterally and inferiorly. The bone was decalcified proximally. Close to the distal head in the medulla there was a dense area of calcification within a radiolucent area. The metatarsal bone was increased in size. There was calcification of the blood vessels and local soft tissue swelling. A chest plate demonstrated calcified areas in the right upper lung just below the clavicle that were consistent with an old tuberculous lesion; there was no evidence of active disease. The lungs were otherwise clear. The heart was not remarkable.

Two days after admission a small fluctuant area developed on the lateral aspect of the right foot in the area of swelling. A small amount of serosanguineous fluid was aspirated, and this was negative for any specific organism, both on smear and culture.

An operation was performed on the eighth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. WALLACE: May I see the x-ray films?

DR. RICHARD SCHATZKI: I should describe this as cystlike destruction in the proximal half of the fifth metatarsal. The cortex is broken through in places, and there is coarse new-bone formation, which is perpendicular to the direction of the bone. The rays of new bone are thicker than those that one usually sees in osteogenic sarcoma. There is also soft-tissue swelling, and a localized area of increased density in the distal portion of the involved metatarsal that looks like an osteochondroma.

DR. WALLACE: Is there a fracture in the bone?

DR. SCHATZKI: No fracture is visible. There may well be one in that area, but the cortex is gone and no definite fracture is visible.

DR. WALLACE: The other bones are negative. Is there evidence of metastatic disease in the chest?

DR. SCHATZKI: No.

DR. WALLACE: The x-ray films are not helpful. We have a woman in her sixties with pain in the right foot of three months' duration and x-ray findings of a cystlike destructive lesion. Can this be a manifestation of some metabolic disease, such as parathyroidism? There is no other evidence for that. Just as a passing thought I shall mention gout. The x-ray films do not suggest it, and there were no tophi or other suggestive findings.

Could this be a syphilitic lesion? She is said to have had gonococcal ophthalmia. However, the patient denied venereal disease in its usual form, and the single blood Hinton test was reported to be negative. I believe that with a queer lesion of this sort, even with one negative Hinton test, we should continue to bear in mind syphilis as a possibility. Certainly the lesion is not characteristic.

Could this be a manifestation of sarcoid, with a lesion in the single bone? She is said to have had a negative chest plate.

DR. SCHATZKI: The chest plate is negative for metastatic disease. There is evidence of old tuberculosis.

DR. WALLACE: That rules out sarcoid. Xanthoma is a possibility, but multiple bones are usually involved.

The pain followed by swelling is suggestive of fracture. There is no story of recent trauma but if there had been a fracture it would have been a pathologic fracture. I am not sure that we can rule it out even by looking at the x-ray films. A fracture might account for some of the new-bone formation.

She had a normal temperature and white-cell count; in addition, some serosanguineous fluid was aspirated that contained no organisms on smear or culture. We should be able to rule out osteomyelitis on the basis of these findings. There may have been metastatic disease in this area, but again that is unlikely. It would be difficult to explain the x-ray findings on the basis of metastatic disease alone, because in general such lesions show punched-out areas of destruction of bone without new-bone formation.

Could this have been due to a tumor of the lymphoma series? Since there is no mention of nodes in general, we must assume they were not large enough to have come to anyone's attention. In considering the lymphoma series our attention is called to the differential count, which had a high proportion of lymphocytes. That does not establish the diagnosis, however.

Could this have been a benign bone cyst not related to a general disease? They are usually solitary and are not of common occurrence in this location. The question of chondroma also comes up. The increased density, as Dr. Schatzki said, is suggestive of a localized chondroma. That appearance could also be caused by multiple chondromas.

With bone proliferation we should think of Ewing's sarcoma, although, of course, the x-ray picture is not characteristic. The localized areas of bone proliferation with ray formation are suggestive of osteogenic sarcoma. Only one small area, however, looks like the ray formation that we so frequently see.

There is considerable evidence that this patient has had and perhaps has active tuberculosis. There were definite x-ray signs of healed tuberculosis. The white-cell and differential counts were, I believe, consistent with that disease, and she had a markedly positive tuberculin test with a dilution of 1:1000. Tuberculosis of bone is generally a destructive lesion and usually has its origin in the region of the joints rather than in the shaft of the bone, as appears to be the case here; however, I do not believe that we can rule it out.

Since this lesion is characteristic of nothing and I must speculate about it, and since there is more

evidence for tuberculosis than for anything else I shall make that diagnosis, with the reservation that it may have been one of a good number of lesions

DR TRACY B. MALLORY: Dr Schatzki would you like to express a further opinion?

DR SCHATZKI: I remember that we were puzzled by the case. The ray formation was a little similar to what we had seen in low grade infection. I do not remember what the final outcome was, so I am quite unbiased. I believe that the visible osteochondroma is significant and that the lesion turned out to be malignant tumor of bone, at least that is what I should call it now.

DR CHANNING C. SIMMONS: Dr Wallace has covered the possibilities well. In considering bone diseases, I like to divide them into four groups: generalized skeletal diseases, such as parathyroid disease and lymphoma; inflammatory diseases, such as syphilis, tuberculosis and osteomyelitis; primary bone tumors; and secondary or metastatic bone tumors.

Sarcoma is practically unknown in people over fifty, except in the presence of Paget's disease, and benign bone tumors are painless. Therefore I think primary bone tumors can be ruled out. A generalized skeletal disease can be excluded by the general examination. Metastatic tumors usually do not give this picture but can look like anything, just as lymphoma of the bone can simulate any other disease. My inclination is to consider this an inflammatory condition, possibly tuberculosis on the strength of the lung condition. The x-ray picture is not characteristic of any particular disease. The facts that she had pain and that fluid was obtained on tap, together with the high lymphocyte count, also suggest tuberculosis. One would have to repeat the blood Hinton test several times before syphilis could be excluded.

DR MALLORY: Three opinions were expressed on the ward. Chronic osteomyelitis was put down

as the first choice, the second was tuberculosis, and the third was bone tumor, type unclassified.

CLINICAL DIAGNOSIS

Chronic osteomyelitis

DR WALLACE'S DIAGNOSIS

Tuberculosis of metatarsal

A TYPICAL DIAGNOSIS

Chondrosarcoma of metatarsal

PATHOLOGICAL DISCUSSION

DR MALLORY: The lesion was explored, and a destructive process was found in the metatarsal. Some material was curetted out, which on frozen section a chondromatous structure following that the entire metatarsal was involved. The final histologic diagnosis was a low grade chondrosarcoma of the metatarsal.

It is difficult to draw a dividing line microscopically between benign and malignant tumors of bone.

Tumors that can behave in malignant fashion often look benign under the microscope. The one was sufficiently atypical so that I thought it to be called malignant. Moreover, it had destroyed the cortex and we found some small masses of cartilaginous tissue in the soft parts around the bone.

The wound was closed, and the patient was allowed to go home. She is returning to the hospital from time to time for observation. As yet no one has seriously raised the question of amputation although that is still under consideration.

DR SCHATZKI: Was there any infection present? If not, the x-ray picture rules out benign tumor.

DR MALLORY: The tumor had definitely destroyed the cortex.

DR SIMMONS: I should rule out benign tumor on the mere fact that the patient had pain.

Two days after admission a small fluctuant area developed on the lateral aspect of the right foot in the area of swelling. A small amount of serosanguineous fluid was aspirated, and this was negative for any specific organism, both on smear and culture.

An operation was performed on the eighth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. WALLACE: May I see the x-ray films?

DR. RICHARD SCHATZKI: I should describe this as cystlike destruction in the proximal half of the fifth metatarsal. The cortex is broken through in places, and there is coarse new-bone formation, which is perpendicular to the direction of the bone. The rays of new bone are thicker than those that one usually sees in osteogenic sarcoma. There is also soft-tissue swelling, and a localized area of increased density in the distal portion of the involved metatarsal that looks like an osteochondroma.

DR. WALLACE: Is there a fracture in the bone?

DR. SCHATZKI: No fracture is visible. There may well be one in that area, but the cortex is gone and no definite fracture is visible.

DR. WALLACE: The other bones are negative. Is there evidence of metastatic disease in the chest?

DR. SCHATZKI: No.

DR. WALLACE: The x-ray films are not helpful. We have a woman in her sixties with pain in the right foot of three months' duration and x-ray findings of a cystlike destructive lesion. Can this be a manifestation of some metabolic disease, such as parathyroidism? There is no other evidence for that. Just as a passing thought I shall mention gout. The x-ray films do not suggest it, and there were no tophi or other suggestive findings.

Could this be a syphilitic lesion? She is said to have had gonococcal ophthalmia. However, the patient denied venereal disease in its usual form, and the single blood Hinton test was reported to be negative. I believe that with a queer lesion of this sort, even with one negative Hinton test, we should continue to bear in mind syphilis as a possibility. Certainly the lesion is not characteristic.

Could this be a manifestation of sarcoid, with a lesion in the single bone? She is said to have had a negative chest plate.

DR. SCHATZKI: The chest plate is negative for metastatic disease. There is evidence of old tuberculosis.

DR. WALLACE: That rules out sarcoid. Xanthoma is a possibility, but multiple bones are usually involved.

The pain followed by swelling is suggestive of fracture. There is no story of recent trauma but if there had been a fracture it would have been a pathologic fracture. I am not sure that we can rule it out even by looking at the x-ray films. A fracture might account for some of the new-bone formation.

She had a normal temperature and white-cell count; in addition, some serosanguineous fluid was aspirated that contained no organisms on smear or culture. We should be able to rule out osteomyelitis on the basis of these findings. There may have been metastatic disease in this area, but again that is unlikely. It would be difficult to explain the x-ray findings on the basis of metastatic disease alone, because in general such lesions show punched-out areas of destruction of bone without new-bone formation.

Could this have been due to a tumor of the lymphoma series? Since there is no mention of nodes in general, we must assume they were not large enough to have come to anyone's attention. In considering the lymphoma series our attention is called to the differential count, which had a high proportion of lymphocytes. That does not establish the diagnosis, however.

Could this have been a benign bone cyst not related to a general disease? They are usually solitary and are not of common occurrence in this location. The question of chondroma also comes up. The increased density, as Dr. Schatzki said, is suggestive of a localized chondroma. That appearance could also be caused by multiple chondromas.

With bone proliferation we should think of Ewing's sarcoma, although, of course, the x-ray picture is not characteristic. The localized areas of bone proliferation with ray formation are suggestive of osteogenic sarcoma. Only one small area, however, looks like the ray formation that we so frequently see.

There is considerable evidence that this patient has had and perhaps has active tuberculosis. There were definite x-ray signs of healed tuberculosis. The white-cell and differential counts were, I believe, consistent with that disease, and she had a markedly positive tuberculin test with a dilution of 1:1000. Tuberculosis of bone is generally a destructive lesion and usually has its origin in the region of the joints rather than in the shaft of the bone, as appears to be the case here; however, I do not believe that we can rule it out.

Since this lesion is characteristic of nothing and I must speculate about it, and since there is more

in England, particularly through the latter's Mental Health Emergency Committee. Total disbursements for 1942 for all purposes totaled nearly \$2,000,000.

The loss of key investigators, especially those engaged in clinical research, to the military and naval services has necessarily forced the curtailment or suspension of some projects, but the Commonwealth Fund has carried on with vigor its multifarious activities in medical education, rural hospitals and public health. A grant was made to the Long Island College of Medicine to pay for visiting instructors from other medical schools; ten fellowships for advanced study were awarded to junior instructors and staff members of medical schools and teaching hospitals. At several colleges the Fund subsidized special teaching units to acquaint pediatricians with the psychologic needs of sick children. Fifteen fellowships were offered to physicians and public-health workers from Latin American countries for postgraduate study in the United States. The outstanding research activities last year were related to respiration, renal function, the control of infectious diseases in armies, the epidemiology of poliomyelitis and the hereditary factors in the incidence of rheumatic fever.

The Commonwealth Fund has every reason to be proud of its solution of the problem of contributing fully to the war effort without the sacrifice of gains already made in nonmilitary fields. In short, it continues to carry forward, in war as in peace, the high purposes of its founder.

MEDICAL EPONYM

STOKES'S COLLAR

William Stokes (1804-1878) first described this phenomenon in the *Dublin Journal of Medical and Chemical Sciences* (5:400-440, 1834), in an article entitled "Researches on the Diagnosis and Pathology of Aneurysm." He discusses a case of aneurysm of the aorta as follows:

I was at once struck with the peculiar appearance of the neck. This was generally enlarged (giving the idea of the patient's wearing a collar or tippet), the jugular veins were turgid and tortuous.

He also mentions the phenomenon in the first part of *A Treatise on the Diagnosis and Treatment of Diseases of the Chest* (Dublin, 1837 — page 231) and again in *The Diseases of the Heart and the Aorta* (Dublin, 1854 — page 573), as follows:

As an indication of intrathoracic tumor, an extremely varicose state of the superficial veins of the neck and thorax is probably less frequent in aneurismal than in cancerous diseases. The pressure may be exercised on the venae innominae or the superior cava. . . . In other cases we find that in place of the large tortuous veins ramifying on the surface, there is a puffy elastic swelling of the entire neck. To this may be given the name of tippet-like swelling of the neck.

R. W. B.

RESOLUTION ON DEATH OF JOHN JOSEPH LUCY

Dr. John J. Lucy, late assistant visiting surgeon on the Second Surgical Service of the Boston City Hospital, died on December 28, 1942, in his forty-eighth year. He had been ill only about two months. He was born in Boston, and was graduated from Boston College and from Harvard Medical School. He took a surgical houseofficership at the Boston City Hospital, followed by a houseofficership at the Boston Lying-in Hospital. He was appointed to the Surgical Staff of the Boston City Hospital in 1925, having had the rank of assistant visiting surgeon for some years prior to his death. He was a member of the Surgical Staff of the Cambridge Hospital, being chief of one of the surgical services at that institution at the time of his death. He was a member of the American Medical Association, the Massachusetts Medical Society, the American College of Surgeons and the Boston Surgical Society, and for many years conducted a large private surgical practice.

He married Miss Alice L. McManus; this marriage was an exceedingly happy one, being blessed with seven children: four daughters and three sons, all of whom are living. In addition to his widow and children he is also survived by his mother.

Doctor Lucy was a man of real character, possessing the highest of principles, both professionally and personally. Loyalty was one of his outstanding qualities. In addition, he was endowed with a natural sympathy and understanding which endeared him to his fellow physicians, to his patients and to his friends. His loss to the profession and the community is indeed a great one.

BE IT RESOLVED, That in the death of Doctor Lucy the Staff of the Boston City Hospital has lost one of its most capable and conscientious members; and

BE IT RESOLVED, That the Staff of the Boston City Hospital express its most sincere sympathy to the family of Doctor Lucy; and

BE IT FURTHER RESOLVED, That these resolutions be placed upon the records of the Boston City Hospital and that the secretary be directed to send a copy to the family of Doctor Lucy and a copy to the *New England Journal of Medicine*.

WILLIAM P. BOARDMAN, *Secretary*
Executive Committee, Senior Staff
Boston City Hospital

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON MATERNAL WELFARE

IMPRESSIONS CONCERNING THE MATERNAL MORTALITY STUDY FROM 1937 TO 1941

The maternal-mortality study that the Section of Obstetrics and Gynecology of the Massachusetts Medical Society has carried on for the State Department of Public Health has been concluded. In some respects it is the most laudable study of this kind that has ever been carried on in the United States.

Many inquiries have been made concerning how this study was conducted. The start is the death certificate, which is signed by the physician and gives the cause of death. In Massachusetts the certificate is then taken to the office of the board of health of the town or city in which the death occurred and is then recorded and filed by the town or city clerk. According to regulations, a copy of each certificate should be filed at the office of the Secretary of State by the tenth of the month following the death; however, in some communities where there are few deaths the copies of the certificates are sent to the State House only at infrequent intervals. Each certificate that reaches the office of the Secretary of State is reviewed by a lay person, and the necessary corrections are made. Before it is filed it is coded by a lay person according to the international classification of deaths, and all deaths occurring within ninety days of childbirth are automatically classified as maternal deaths. All such deaths are reviewed by an investigator from the Department of Public Health, who is a registered physician. He makes a copy of each certificate covering a maternal death on a questionnaire prepared by the Children's Bureau of the United States Department of Labor, the front page of which has a replica of the death certificate. During the period of study, copies of these questionnaires were sent to the committee of the Massachusetts Medical Society. The com-

mittee in turn forwarded them to members of the Society in different parts of the State who were doing obstetrics, so that personal interviews with the physicians signing the death certificates might be held. It was hoped that these questionnaires might reach the investigators within, at most, two months of the day of death so that the interviews might be held when the facts were fairly clear in the minds of the attending physicians. In many cases, however, it was impossible to have these deaths investigated as soon as it was hoped they could be. Some certificates were filed at the State House many months after the death. Often by the time the investigator approached the physician whose name was on the certificate, it was found that the physician had left to join the armed forces, so that a personal interview was impossible. Some of the investigators were so busy with their work and the work of others that months elapsed before investigations were started. After the cases had been investigated, the reports were returned to the committee and formed the basis for the figures that have appeared in the *Journal*.

The mechanism of the study was not perfect, but as has already been said, the results are probably as good, if not better, than those obtained in any part of this country. A much more ideal set-up would be to appoint an obstetrician, either a young or an older man with plenty of time on his hands, who could personally investigate each death, irrespective of in what part of the state it occurred, within two months of the date of the death. This investigator with a committee of five should go over the cases and allocate them to such headings as were agreed on by all. In the present study the allocation of the cause of death was done by one obstetrician. Had the cases been gone over by a committee it is quite possible that some of the doubtful cases would have been classified differently. If one man with plenty of time on his hands were to conduct such an investigation he could inquire into many details that were not taken into consideration in the present investigation. Frequently a record was not so valuable as it might have been because no mention was made of the duration of pregnancy. Often no mention was made whether a living child was obtained. Circumstances, perhaps beyond the control of anyone, frequently led to records that were lacking in essential information. Such an investigation as this is no stronger than its weakest link.

The study has brought out several facts that show the weakness of the system and the inaccuracy of the figures. So long as it is the policy to include every fatality occurring within ninety days of childbirth as a maternal death, these sta-

tistics, from the point of view of obstetrics, will obviously be misleading. They will show the actual number of mothers who died, but among that number will be many whose deaths had nothing to do with obstetrics. For the figures to mean what they should, patients who die within ninety days of childbirth and whose deaths are found to be nonobstetric should be eliminated. An example of this is a patient who died of asthma brought on by allergy to aspirin.

In Massachusetts, it is perfectly possible, although commonly unrecognized, to change the cause of death on the original certificate when it is proved to be untrue. This may be done by the physician who signed the certificate provided he is able to present proof of its inaccuracy. This flaw in the vital statistics applies to all branches of medicine and surgery. Not infrequently, a patient who dies in a hospital has as the cause of death on the certificate a diagnosis that has been proved by autopsy to be incorrect. If the institution in which this death occurred made application to the office of the Secretary of State, the incorrect certificate could easily be rectified. Such a routine procedure would make vital statistics in Massachusetts more accurate than they are at present. This can and should be done.

In this state, all sudden deaths and those with a questionable cause must be referred to the medical examiner before the body may be buried. Since the medical examiner in the course of a year sees a number of maternal deaths, by applying to the district attorney for permission to perform an autopsy in cases in which the exact cause of death is unknown, he would be able to make an exact anatomical diagnosis. If this were done more frequently than it is, the statistics would be improved.

Another cause of inaccuracy is the fact that an incorrect diagnosis is sometimes written on the death certificate. This is partly due to ignorance, and partly to sentiment. An embolus, in the lay mind, has long been looked on as an act of God. "Hemorrhage and shock" are not pleasant terms to convey to the stricken family. It is gratifying that fewer questionable causes of death were found as the study progressed.

It is not fair to attribute all the improvement in the rate of the maternal mortality in Massachusetts during the past five years to this study. Nevertheless, the study has brought obstetrics into the open, and has made physicians conscious that their work is under scrutiny. The diminution in the number of maternal deaths in which bungling obstetrics played a part shows either that physicians are more expert or that they are more careful. At the beginning of the study, some of the doctors

resented an interview, since they believed that their privacy was being violated; this attitude no longer exists. Toward the end of the study, the co-operation between the general practitioner and the investigators was excellent. This study has also made the trustees of hospitals conscious of their responsibilities. They have at last learned to appreciate that their obligations to patients in hospitals extend to the medical care of those patients, and, in some instances, they have insisted that the practice of obstetrics should be supervised and that abnormal cases should be handled only by trained men. This achievement alone has made the study worth while.

The study has also brought out the fact that many women, either through ignorance or through stubbornness, do not receive adequate prenatal care. This is deplorable and warrants intensive educational propaganda.

In conclusion, the committee expresses its thanks for the co-operation that the physicians of Massachusetts have shown. It also expresses its deep appreciation for the willingness of those physicians who have served as investigators in these cases; the facts that they gathered, often under burdensome circumstances, have made the study possible.

* * *

The above paragraphs conclude the series of articles on the causes of maternal death that have been carried weekly in the *Journal* for the past four and a half months.

In the March 11 issue of the *Journal*, the Committee on Maternal Welfare will begin the presentation of a series of cases at two-week intervals. Half of these will concern instructive obstetric cases, and half will illustrate the proper handling of interesting and unusual neonatal cases.

DEATH

LEONARD — EDWARD J. LEONARD, M.D., of Dorchester, died February 15. He was in his forty-second year.

A native of Dorchester, Dr. Leonard received his degree from Georgetown Medical School in 1936. He had an internship at Mercy Hospital, Baltimore. He served on the staffs of the Carney Hospital and St. Margaret's Hospital. He was a member of the Massachusetts Medical Society, the American Medical Association and the Dorchester Medical Society.

His widow, four children, two sisters and two brothers survive him.

WAR ACTIVITIES

CIVILIAN DEFENSE

NURSING EXECUTIVES FOR EMERGENCY BASE HOSPITALS

To ensure adequate supervision of nursing service in emergency base hospitals, Surgeon General Parran of the United States Public Health Service has authorized the

appointment of a limited number of nurses with supervisory and administrative experience to serve as nursing executives, according to a recent announcement by the Medical Division of the United States Office of Civilian Defense.

Emergency base hospitals are institutions in relatively safe areas, adjacent to probable target areas, designated by the Medical Division to receive civilian casualties or other hospitalized persons from casualty receiving hospitals in the event of a grave wartime emergency.

The appointment of these nursing executives will follow in general the method that is being used in the appointment of physicians who, as members of affiliated hospital units, will hold inactive reserve commissions in the United States Public Health Service and will be called to active duty in emergency base hospitals only when additional staff is needed because of a war emergency.

Nurses recruited under this program may be assigned by the state chief of Emergency Medical Service to serve at emergency base hospitals either individually or with affiliated units. They may supervise a newly created nursing service or supplement the existing supervisory staff of an institution.

The nurses will be offered appointments in the United States Public Health Service as consultants on an inactive status and will be called to active duty by the Surgeon General on the recommendation of the state chiefs of Emergency Medical Service and regional medical officers only if their services are required at emergency base hospitals because of a military necessity, the circular states. When on duty they will be entitled to payment by the United States Public Health Service according to their experience and qualifications.

The circular authorizes the number of nurses to be recruited in each state for this purpose to be twice the number of affiliated hospital units actually being formed in the state. Although their appointments will obligate them to serve in an emergency base hospital in their regions if called to duty by the Surgeon General in a wartime emergency, they may resign their appointments at any time to accept assignments in the Army or Navy.

MISCELLANY

AMERICAN COLLEGE OF SURGEONS

New developments in military and civilian medical and hospital service will be brought to members of the medical profession at large and to hospital representatives through a series of twenty War Sessions, beginning March 1, to be held throughout the United States under the sponsorship of the American College of Surgeons with the co-operation of other medical organizations and of the Federal medical services.

Each session will consist of an all-day program, lasting from 9:00 a.m. to 10:00 p.m., including luncheon and dinner conferences. There will be eight meetings in each session, four of which will be for the entire assembly; the remainder will be divided into two meetings each for physicians and for hospital representatives. Subjects will be changed in the different states and service commands. Nationally known representatives of the United States Army, the United States Navy, the United States Office of Civilian Defense, the United States Procurement and Assignment Service and the United States Public Health Service will address the meetings and will lead the dis-

cussions, in addition to participation by prominent leaders in civilian medical practice and hospital service.

The topics relating to military medicine to be discussed will include care of the ill and injured in combat zones and after evacuation. The newer types of injuries encountered in this war, such as crush and blast injuries, will be especially considered, together with the prevention and treatment of infections, the treatment of burns and shock and the care of injuries of specific parts of the body. Anesthesia, plastic surgery and the psychoneuroses of war will be some of the other topics. The problems of civilian medical care in wartime will include the following: the responsibilities of individual physicians and hospitals; the personnel problems of hospitals; the organization of emergency medical services; the maintenance of adequate supplies, furnishings and equipment; the preservation of high standards of medical and nursing education and of hospital service in general; hospital public relations; and the necessary administrative adjustments in professional staffs of hospitals. The opening meeting of each session will be devoted to a discussion of the medical and surgical aspects of chemical warfare, led by a representative of the United States Office of Civilian Defense, and the closing meeting will be a panel discussion on problems in wartime civilian medical practice, led by representatives of the United States Public Health Service, the American College of Physicians, the American Medical Association, medical services in industry and the American College of Surgeons. Other topics for consideration at this meeting include endemic and epidemic diseases, medical services in industry, medical and surgical practice, and supplementary postgraduate education for medical officers and civilian physicians.

The schedule for the sessions is as follows:

	CITY	STATES AND PROVINCES	HEADQUARTERS
March 1	St. Paul	Minnesota, North Dakota, South Dakota	Lowsy Hotel
" 3	Milwaukee	Wisconsin, Illinois	Schroeder Hotel
" 5	Indianapolis	Indiana, Kentucky, Ohio	Claypool Hotel
" 8	Detroit	Michigan	Statler Hotel
" 10	Pittsburgh	Pennsylvania, West Virginia	The William Penn
" 12	Buffalo	New York, Ontario	Statler Hotel
" 15	Boston	Massachusetts, Connecticut, Maine, New Hampshire, Rhode Island, Vermont	Statler Hotel
" 17	Brooklyn	New York City, Delaware, New Jersey	St. George Hotel
" 19	Richmond	Virginia, District of Columbia, Maryland	John Marshall Hotel
" 22	Charlotte	North Carolina, South Carolina	Charlotte Hotel
" 24	Birmingham	Alabama, Florida, Georgia	Futwiler Hotel
" 26	Memphis	Tennessee, Arkansas, Mississippi	Peabody Hotel
" 29	Houston	Texas, Louisiana	Rice Hotel
April 1	Kansas City	Kansas, Missouri, Oklahoma	President Hotel
" 3	Omaha	Nebraska, Iowa	Fontenelle Hotel
" 6	Denver	Colorado, New Mexico, Wyoming	Cosmopolitan Hotel
" 9	Salt Lake City	Utah, Idaho	Utah Hotel
" 13	Los Angeles	Southern California, Arizona	Biltmore Hotel
" 16	San Francisco	Northern California, Nevada	Fairmont Hotel
" 20	Seattle	Washington, Montana, Oregon, British Columbia	Olympic Hotel

Dr. Irvin Abell, chairman of the Board of Regents of the American College of Surgeons, in announcing the War

Sessions, said that although participating states and provinces for each meeting have been designated to facilitate arrangements, there will be no geographic restriction on attendance, and those who plan to attend may select the place and time which are most convenient.

The American College of Surgeons canceled its 1942 national meeting and is holding in abeyance plans for a clinical congress in 1943. The regional meeting plan provided by the War Sessions is offered to save the time of physicians and other personnel, and to minimize transportation difficulties, without sacrificing unduly the educational and stimulative benefits of medical assemblies.

CORRESPONDENCE

NEED FOR MEDICAL OFFICERS

To the Editor The need for physicians in the armed forces continues unabated. A large number must be made available from New England in the near future, and since the small communities have done more than their share, many of the future medical officers must come from metropolitan areas.

Physicians of the older age group—forty to fifty—have volunteered freely as have many younger men, yet there is a tendency for some of the latter to wait until called for.

The chief worry on the part of doctors volunteering for the Navy has been a financial one. Yet insufficient attention is paid to the fact that overhead and incidental expenses are immediately cut on entry into service to a degree that largely compensates for the loss of gross cash income received before. Furthermore, the Soldiers and Sailors Relief Act of 1940 protects an officer, his house and his family if he can show that his net income has been substantially reduced.

It is also frequently said that physicians well trained in one field are assigned to duties for which they are ill fitted or which are beneath their professional ability. Although instances of this character do exist, it must be recognized that the exigencies of war may in certain cases render such waste temporarily necessary and, further, and more important, that every effort is made to allocate a man to that position for which he is best fitted. This is the definite, stated policy of the Surgeon General, and it is followed so far as is humanly possible.

The further objection has been raised that often for many months a previously busy physician is comparatively inactive after having been commissioned. Such bore some waiting stems in part from the necessary and vital indoctrination of the Navy and in part from the difficult problem of proper allocation of the individual. Line officers and enlisted men are equally confronted with the same problem.

I urge every physician of military age to volunteer for the Army or the Navy. Whether he is or is not truly essential in civil life can and should be objectively decided by the Procurement and Assignment Service. Those who volunteer will indicate their loyalty to their country and their faith in their fighting comrades.

Applications of interns and residents may be accepted before clearance by the Procurement and Assignment Service if availability is anticipated within twelve months.

If any physician cares to discuss matters concerning his opportunities in the United States Naval Reserve, I shall

be pleased to consult with him any day except Sunday between the hours of 8 00 a m and 3 30 p m

VERSION EXTRAORDINARY

To the Editor The following quotation is from Herman Melville's *Moby Dick*, a work especially dear to those New Englanders who were born close to salt water. In the annals of obstetrics this case is surely one of the most remarkable.

Queequeg has just delivered Tashtego from the head of the sperm whale. The quotation follows:

Both! both!—It is both!—cried Diggoos again with a joyful shout and soon after, Queequeg was seen boldly striking out with one hand, and with the other clutching the long hair of the Indian. Drawn into the waiting boat, they were quickly brought to the deck, but Tashtego was long in coming to and Queequeg did not look very brisk.

Now, how had this noble rescue been accomplished? Why, diving after the slowly descending head, Queequeg with his keen sword had made side lunges near its bottom, so as to scuttle a large hole there, then dropping his sword, had thrust his long arm far inwards and upwards, and so hauled out our poor Tash by the head. He averred, that upon first thrusting in for him, a leg was presented, but well knowing that that was not as it ought to be, and might occasion great trouble,—he had thrust back the leg, and by a dextrous heave and toss, had wrought a somerset upon the Indian, so that with the next trial, he came forth in the good old way—head foremost.

And thus, through the courage and great skill in obstetrics of Queequeg, the deliverance, or rather delivery of Tashtego was successfully accomplished, in the teeth too of the most untoward and apparently hopeless impediments which is a lesson by no means to be forgotten. Midwives should be taught in the same course with fencing and boxing, riding and rowing.

NURSES FOR THE ARMED FORCES

To the Editor The careful analysis of the nursing situation by Dr Robert T Monroe, as reported in the January 14 issue of the *Journal*, merits the attention of every physician. The fact of the matter is that we are in a serious predicament and none of the solutions suggested sounds hopeful to me.

We have been altogether too easy in allowing without protest the loss of so many nurses. For after all the greatest amount of illness is not among the armed forces, but right here at home. In fact if the home front is not adequately protected by both doctors and nurses, our output of war materials will be seriously curtailed. With the flight of the practical nurse to more lucrative fields in industrial plants, we cannot afford further weakening of our nursing service despite the demands of the armed

forces. My solution is that enlisted men be trained as nurses by a short intensive course, which will equip them quite as well for nursing as the pharmacist's mate is equipped to take over the medical and surgical care of the men on ships where there are no medical officers. To get this practical and feasible suggestion into actual execution will require considerable effort because of the rigid mental processes of the military. But the civilian has had to change his whole scheme of living, and there is no reason why the military powers-that-be should not cut the pattern according to the cloth. For even though there are ten million men in the armed forces, there are one hundred and twenty million civilians at home.

BOOK REVIEWS

Surgery of Modern Warfare. By sixty-five contributors. Edited by Hamilton Bailey, F.R.C.S. In two volumes. Vol. II. 4°, cloth, 899 pp., with 325 illustrations. Baltimore: The Williams and Wilkins Company, 1941. \$10.00.

This volume is a continuation of the first one, which has already been reviewed in this column. The general principles of war surgery, with some special sections, were discussed in the first volume. The second volume completes the work on fractures and amputations and considers war surgery of the head, neck and brain.

The material presented has obviously not been written for the specialist in the base hospital, but rather for the officer who starts the patient on his way back from the front. Without a knowledge of what must and can be done in particular cases, it is often difficult for the front-line medical man to make decisions regarding individual cases.

The material included is so varied and extensive that one hesitates to single out any parts for mention. The best of civilian surgery has been taken by a group of experts and adapted to war conditions as their own experience dictates. The chapters on organization of medical service close to the front are fully as important as the rest of the two volumes, for the quality of surgery in war depends greatly on having the man who knows in the right place.

Electrotherapy and Light Therapy, with the Essentials of Hydrotherapy and Mechanotherapy. By Richard Kovacs, M.D. Fourth edition. 8°, cloth, 735 pp., with 314 illustrations and 1 color plate. Philadelphia: Lea and Febiger, 1942. \$8.00.

Seventy-four illustrations were eliminated from the fourth edition of this book on the ground that they were obsolete. For the same reason, similar treatment should have been accorded to the title of the book. "Physical therapy" is a more comprehensive term and one more commonly used for texts of the category to which this treatise belongs. Such a change became even more appropriate when the extra chapters on hydrotherapy, massage and exercises were added, none of which belong to the realm of electrotherapy and light therapy.

The text itself is justly deserving of the popularity that it is apparently enjoying. This is manifested by the fact that within ten years it has run through four editions. Such accomplishment has been made possible by the author's constant vigilance for every form of

progress made in this field. Another factor contributing to the value of this book is the fact that Dr. Kovacs enlisted the aid of several competent men to collaborate with him—each one in his particular field. The result is a comprehensive and an authoritative textbook on physical therapy.

On the whole, good judgment was used in rearranging the material, eliminating some illustrations and diagrams and adding new ones. This is particularly true in the section dealing with short-wave and long-wave diathermy, particularly regarding the underlying theories of electrophysics. The latter is a subject that is confusing and annoying to many an earnest physician who dislikes empiricism. Much more light is needed to clarify short-wave currents—a relatively new physical agent.

Not all changes, however, have been for the better. Thus, the glossary in the preceding editions, which occupied fifteen pages, was a valuable source of information. The reason for its omission from the present edition, which is nine pages shorter than its predecessor, is not evident. Its restoration in future editions will be welcome.

Vaginal Hysterectomy. By James W. Kennedy, M.D., and Archibald D. Campbell, M.D.C.M., F.R.C.S. (Can.), F.R.C.O.G. 4°, cloth, 495 pp., with 44 illustrations. Philadelphia: F. A. Davis Company, 1942. \$10.00.

This book is written by two authors, both of whom use vaginal hysterectomy extensively. The senior author, Dr. Kennedy, is an extremist and enthusiast who is almost on a crusade for vaginal hysterectomy. Dr. Campbell begins his part with a discussion of the anatomy of the female pelvis, and limits his indications to those patients who have a damaged birth canal and need hysterectomy. The authors state that they do not consider vaginal hysterectomy a substitute for abdominal hysterectomy in all cases, but they do emphasize most properly that this procedure has fallen into disrepute in many places simply because a teacher has condemned it through a lack of experience with it. To quote: "We have preceded the general discussion of vaginal hysterectomy by the above admonitions for the reason that we know of no subject in major surgery about which so many ignorant and ignoble statements have been made by teachers as that concerning vaginal hysterectomy."

The indications for this operation that are enumerated by the senior author are without question proper in his hands. However, in the opinion of the reviewer, the use of a surgical procedure must be governed by the ability and training of the surgeon. If one begins to master hysterectomy via the vaginal route by first applying it in prolapse and procidentia, then one may in time so perfect his technic that the operation may be safely used to remove the fibroid uterus. In such matters each surgeon must be the judge of his own limitations and no rules can be stated for his conduct. One can say categorically that various procedures give the same end result in the hands of different operators, for example, the operations for prostatectomy. The lesson of his work is that vaginal hysterectomy should have a place in the repertoire of all those who treat gynecologic patients, and when one becomes expert at it, its indications may be extensive.

There are excellent illustrations of both the clamp and suture methods, and all details of technic are clearly presented. This is a book that should be the library of all who do gynecologic surgery.

NUMBER 9

THE RENAL COMPLICATIONS OF LEUKEMIA

DUDLEY MERRILL, M.D.,¹ AND HENRY JACKSON, JR., M.D.²

CAMBRIDGE AND BOSTON, MASSACHUSETTS

ALTHOUGH many authors¹⁻⁶ have commented on the frequency of leukemic infiltration of the kidneys at some time during the course of the disease, and others^{1, 7-11} have reported the frequency of renal stone and the rare complication of gout,^{1, 10-15} only a few^{7, 8, 16, 17} have suggested taking advantage of these facts in planning x-ray treatment. This is usually of little importance, since all present day methods of treatment in leukemia are merely delaying rearguard actions. However, in an occasional case this knowledge is of benefit to the patient, so that it has seemed worthwhile to call attention once again to these not infrequent complications of a practically invariably fatal disease.

Mach⁶ reported a case of acute myeloid leukemia that at onset showed peripheral edema and urine containing albumin, casts and red and white cells in the sediment, which led to an initial erroneous diagnosis of acute nephritis. There was no azotemia or hypertension. A post-mortem examination showed bilateral leukemic infiltration of the kidneys.

Naegeli¹ has commented on the frequency of "chronic nephritis" in chronic lymphatic leukemia. He has also pointed out the frequency of uric acid stones but the rarity of gout in myeloid leukemia. He, as most other authors on this subject,^{1, 4, 10-15} thinks that the occurrence of gout in leukemia is probably pure coincidence, or that at most the leukemia may be regarded as a contributory factor in a patient with a constitutional predisposition to gout. Bedrna and Polcak⁹ have reported 2 cases of acute ureteral obstruction by uric acid stones complicated by leukemia,—in one myeloid and in the other lymphatic,—in both of which the complication developed shortly following x-ray treatment. In both cases the stones were

removed by ureteral catheterization and the patients were relieved of this acute complication.

Jugenburg and Tschotschia⁷ have reported detailed studies of the uric acid metabolism in patients with leukemia undergoing x-ray treatment. They emphasize the danger of renal failure in these cases, due either to actual leukemic infiltration of renal tissue or to the overloading of kidneys already involved in nonleukemic degenerative lesions, and forced to excrete large amounts of uric acid consequent to the x-ray destruction of high numbers of immature white cells.

One of us (D. M.⁸) has also reported 3 cases of leukemia where renal failure was apparently precipitated by x-ray therapy.

A case of chronic lymphatic leukemia was reported by Cabot¹⁸ in which the patient died seventeen days after the institution of x-ray therapy. The urine showed red and white cells in the sediment, and vomiting began after the first x-ray treatment. The post-mortem examination showed extensive leukemic infiltrations in both kidneys. The course was consistent with death from uremia, but unfortunately no blood-nonprotein-nitrogen or blood-urea studies had been done during life.

In the records of the Pondville Hospital there have been 18 autopsied cases of leukemia during the last nine years. Ten patients had impaired renal function before death. Of these, 4 actually died in uremia (3 of them having nephrolithiasis), 2 others had nephrolithiasis, and 4 had extensive gross and microscopic leukemic infiltration of the kidneys.

The following 3 cases (2 from the Pondville Hospital and 1 from another hospital) are reported in detail in order to emphasize the clinical importance of renal complications in leukemia. Brief abstracts of the 8 other cases from the Pondville Hospital are given at the end of this paper.

CASE REPORTS

CASE 1. H. A. (P.H. 15736), a 61-year-old man, was admitted to the hospital on June 8, 1939, with a diagnosis

¹From the Medical Service, Pondville Hospital, Massachusetts Department of Public Health, Wrentham, Massachusetts.

²Assistant in medicine, Harvard Medical School; visiting physician, Pondville Hospital.

³Assistant professor of medicine, Harvard Medical School; senior visiting physician, Pondville Hospital.

of chronic myeloid leukemia, chronic infectious arthritis and carcinoma of the conjunctiva of the right eye. He had been perfectly well until January, 1937, when one night he suddenly developed burning and itching of the skin of both feet and ankles, lasting about an hour and followed by mild aching in both feet. The next morning both ankles were acutely painful, red, hot, and swollen to about twice their natural size. This initial attack lasted for 2 weeks. From then on there were recurrent attacks of the same type of arthritis, involving first one joint and then another, until it became more or less continuous. The joints most affected were the ankles, knees, right elbow and right wrist. During periods of freedom from pain the patient was able to walk about quite comfortably without crutches or cane. The attacks were never associated with chills, fever or sore throat, and were prone to begin suddenly at night and subside gradually over a period of several days to weeks.

Six months after the first episode of joint pain, the patient had a sudden attack of severe left-sided abdominal cramps, not radiating to the groin or back and not associated with nausea or vomiting. He was admitted to a hospital in another state, where he was discovered to have an enormously enlarged spleen, and after extensive blood and x-ray studies was told that he had an incurable disease for which nothing could be done. However, he felt in his usual excellent health except for the recurrent attacks of joint pain, and so left the hospital against advice. In January, 1939, 6 months before coming to the Pondville Hospital, the patient entered another hospital, where diagnoses of infectious arthritis and myeloid leukemia were made and he was given a course of sixteen x-ray treatments of the spleen without any noticeable effect on the joint pains, which were the only symptoms that bothered him. In May, 1939, the patient was observed to have a white spot on the scleral conjunctiva of the right eye. This grew slowly. A biopsy specimen was diagnosed as epidermoid carcinoma, and he was therefore referred to the Pondville Hospital for x-ray treatment. When admitted he complained only of pain in the joints.

The past history included an episode of profuse bleeding from the gums for 3 days after tooth extractions in 1929, and a similar episode in 1937. Both the parents lived to old age, dying of natural causes. Neither suffered from gout or arthritis.

Physical examination showed a well-developed, fairly well-nourished, plethoric-looking man of 61. Many telangiectases were scattered over the face. There were numerous small tophi in the lobes of both ears, but none were palpable around any of the joints. In the right eye extending over the limbus of the cornea was a small, whitish lesion of the conjunctiva, slightly elevated above the surrounding sclera. The oral mucous membranes were a deep red. There were four remaining badly infected teeth in the lower jaw. The heart and lungs were essentially normal. The blood pressure was 132/85. The spleen was enormously enlarged and extended 3 cm. below the umbilicus and 1.5 cm. to the right of the midline. The liver was also enlarged and extended about 8 cm. below the costal margin. There was a large easily reducible left inguinal hernia, and a smaller one on the right. All the joints appeared to be normal except for the right knee, where there was redness, swelling, heat and fluctuation over the patellar bursa. Both knees were painful on active motion.

Count of white cells and the hemoglobin (Sahli). cc., 31,400,

with 91 per cent polymorphonuclear leukocytes, 2 per cent monocytes, 1 per cent eosinophils, 2 per cent basophils, 2 per cent metamyelocytes and 2 per cent stem cells. The urine was acid, with a specific gravity of 1.020, no albumin and no sugar. The sediment contained innumerable white cells and contained 25 red cells per high-power field. A blood Hinton test was negative. The nonprotein nitrogen was 53 mg., the blood uric acid 8.5 mg., and the creatinine 1.74 mg. per 100 cc. A phenol-sulfonephthalein test showed 25 per cent excretion in the 1st hour and 20 per cent in the 2nd. The basal metabolic rate was +70 per cent. X-ray films of the joints showed no changes characteristic of gout, but microscopic examination of the material obtained from a tophus in the ear lobe showed sodium urate crystals.

Diagnoses of gout, myeloid leukemia and carcinoma of the conjunctiva were made.

The patient remained under practically constant observation from this time until his death on October 31, 1940, approximately 1 year and 5 months later, or 3½ years after the discovery of his splenomegaly.

The conjunctival carcinoma responded to x-ray therapy and was cured in about 1 month's time. The patient's slow downward course was punctuated by increasingly frequent attacks of gout, which responded less and less to colchicine, cinchophen and a diet low in fat and purines. The renal function, which was slightly impaired when he was first studied, diminished steadily. One year after admission phenol-sulfonephthalein excretion had fallen to 5 per cent in 2 hours, though the nonprotein nitrogen still remained around 50 mg. per 100 cc.

Two months before death the white-cell count reached 56,000, and inasmuch as the patient had never reacted well to x-ray therapy, a trial of Fowler's solution was made. In the week following the institution of this treatment the white-cell count dropped to 30,000, but the nonprotein nitrogen rose steadily to 71 mg. per 100 cc. As the patient was clinically on the verge of uremia, the potassium arsenite was stopped and the fluid intake was increased. The nonprotein nitrogen then dropped to 35 mg., but again rose slowly to 63 mg. on the day of death. There was occasional gross hematuria, and almost all the urinary sediments examined had microscopically demonstrable red cells, though there was no clinically recognizable episode of renal colic.

The red-cell count remained between 4,000,000 and 6,000,000 for the first 4 months of observation but then began to fall, and at the time of death was 1,720,000, with a hemoglobin of 20 per cent (Sahli). The white-cell count varied from 12,000 to 60,000, but no differential count showed more than 15 per cent myelocytes.

X-ray treatment was given to the kidneys in the hope of improving the renal function, but no significant benefit could be demonstrated. A course of x-ray treatments was twice given to the spleen, with only slight effect on the white-cell count, and each time with a severe exacerbation of the gout. However, since the patient had had so many attacks of gout and the x-ray treatments were spread out over a week's time, it is impossible to be sure that the latter increased the gout. At all events, the patient was not helped by the x-ray treatment. The trial of Fowler's solution, as mentioned above, resulted in a rapid temporary drop of the white-cell count but coincided with an alarming rise of the nonprotein nitrogen, so that this too was discontinued. The patient finally died with extreme cachexia, profound anemia and chronic renal insufficiency.

Autopsy The spleen weighed 1360 gm, and the liver 2475 gm. The kidneys were of normal size, weighing 110 gm each. There was a large stone in the pelvis of the right kidney, and several small ones in the calyces on the right. There was also a small stone in the lower end of the right ureter just proximal to the opening into the bladder. Microscopic examination of the kidneys showed relatively normal findings except for the presence of masses of leukocytes and myelocytes in the blood vessels and a small area of leukemic infiltration in the cortex. The bone marrow showed the characteristic picture of chronic myeloid leukemia.

In brief, this patient had chronic myeloid leukemia and gout. During his last 4 years of life practically all his symptoms were due to gout, although renal insufficiency was a factor in the last year and a half. An incidental finding was a carcinoma of the conjunctiva of the right eye that was cured by radiation therapy. At autopsy the diagnosis of leukemia was confirmed and multiple renal calculi (pelvic and ureteral) were found that doubtless were a contributory if not the main cause of his impaired renal function. The similarity of this case to the one reported by Reifstein¹⁴ is striking.

CASE 2 E M H (P H 19588), a 28-year-old, married woman, was admitted to the hospital on November 9, 1941, for x-ray treatment on the basis of a previous diagnosis of lymphosarcoma. She had been perfectly well until 4 months previously, when she began to have marked frequency of urination during the day and had to void twice during the night. This continued for 2 months but was not associated with any other symptoms. She felt perfectly well and the frequency gradually disappeared. Six weeks prior to entry she began to have moderately severe lower abdominal pain, chiefly on the left but sometimes in the right groin. The pain came on gradually and lasted for several hours, and was apt to be worse at night. It was sometimes knife-like and severe enough to double her up, but at other times it was merely a dull ache. There was some loss of appetite, and mild indigestion. Occasionally the patient was feverish and once or twice had profuse night sweats. At about the time the abdominal pain began she first noticed some painless swellings in her neck, and subsequently more and more lumps appeared in both sides of the neck and behind the ears. She had also noticed a tendency to bruise more easily than usual in the preceding few weeks, and had been menstruating for 10 days at the time of admission. There had been gradually increasing dyspnea for the preceding 2 months. She had been seen in another hospital, where a lymph node had been removed from the neck for diagnostic purposes. A diagnosis of lymphosarcoma had been made on the section so that she was referred to the Pondville Hospital for x-ray therapy.

The past history included osteomyelitis of the left leg at 7 and removal of the appendix and an ovarian cyst at 24.

Physical examination showed a well-developed, pale, obese woman with masses of discrete firm nodes in both sides of the neck. Enlarged nodes could also be felt in front of and behind both ears, in both axillas and in both groins. The nodes were firm and discrete and varied

in diameter from 0.5 to 2.0 cm. There were purpuric spots on the skin of the chest and left arm. The gums and mucous membranes were pale but showed no hemorrhages. The heart and lungs were within normal limits. The blood pressure was 160/85. The abdomen was distended tympanically, and tender in both lower quadrants. The spleen was felt two fingerbreadths below the costal margin. The legs were obese but there was no pitting edema.

The red-cell count was 1,700,000 and the hemoglobin 30 per cent (Sahli). The white cell count was 4000, with 40 per cent polymorphonuclear leukocytes, 21 per cent lymphocytes, 1 per cent basophils, 4 per cent metamyelocytes and 32 per cent extremely large immature cells, thought to be lymphoblasts. The red cells showed marked variation in size and shape, and occasional nucleated red cells were seen. A blood Hinton test was negative. The urine showed a specific gravity of 1.015, the slightest possible trace of albumin and no sugar. The sediment contained occasional red cells and 8 white cells per high power field, with occasional clumps of the latter. The blood nonprotein nitrogen was 20 mg per 100 cc.

A diagnosis of acute lymphatic leukemia was made. The prognosis was considered extremely grave, but the patient was given repeated transfusions (3500 cc of blood in seven transfusions), and as she continued to bleed from the uterus was given radiation therapy to the pelvis in the hope of stopping the bleeding.

On November 27, 18 days after admission a generalized convulsion occurred and the blood pressure was 240/130. The urine showed a large trace of albumin and many red and white cells in the sediment. The blood nonprotein nitrogen was 66 mg per 100 cc. The patient was drowsy, there was pitting edema of the legs and face, and the eyes were puffy. The nonprotein nitrogen continued to rise, reaching 80 mg on December 1. Because of the possibility that these manifestations of acute nephritis were due to leukemic renal infiltration, a course of x-ray treatments was given to the kidneys. This was followed by improvement, with a gradual drop of the nonprotein nitrogen to 30 mg on December 13. The facial edema gradually cleared, but the edema of the legs remained about the same. The blood pressure had dropped to 170/120 by November 30 and was 180/105 on December 7, when another series of x-ray treatments was begun to the region of the kidneys. There was a slight further drop to 170/110 on December 4 and to 170/90 on December 15, and finally to 110/65 on December 16, the day of death. Thoracostomies were done on December 6 and 13, with the removal of 1800 cc of clear, yellow fluid each time. In spite of the apparent improvement of kidney function the patient failed rapidly and died about 5 weeks after admission. During these weeks the hemoglobin had varied from 30 to 53 per cent (Sahli) and the white cell count from 4000 to 2000. The large, immature white cells varied from 2 to 36 per cent.

Autopsy There were bilateral pleural effusions, enlargement of the spleen (weight 350 gm) and of the liver (weight 1900 gm) and a large retroperitoneal tumor. Around the aorta, in both the thoracic and abdominal portions, there were many enlarged lymph nodes, and in addition there was a diffuse infiltration of the adjacent areolar tissue by yellowish, firm tissue similar in appearance to that of the lymph nodes. This tissue was quite dense and was hard to dissect from the vertebral bodies. Retroperitoneally, particularly in the lower left portion this para-aortic tumor was extensive, completely surround-

ing the great vessels, the renal vessels, both ureters, the adrenal glands and the pancreas, and infiltrating and practically surrounding the pelvic organs. The tumor also extended along the femoral vessels into both legs. The tracheobronchial and mesenteric lymph nodes showed only slight enlargement. No ante-mortem thrombi were found in any of the compressed blood vessels. The kidneys were somewhat enlarged, the right kidney weighing 250 gm. and the left 180 gm., and there were multiple small urate stones in the right kidney, pelvis and calyces. On microscopic examination the kidney sections showed extraordinarily few abnormalities. A section from the left kidney showed slight interstitial fibrosis and tubular dilatation, which were not present on the right. Sections from both kidneys showed normal glomeruli, but in the convoluted tubules there were epithelial swelling and granularity and some nuclear pyknosis. Many tubules contained amorphous material, and a few contained granular casts. The peripelvic tissues showed neoplastic cellular infiltration, but the kidney parenchyma did not. Histologic examination of the tumor masses showed a neoplasm that was diagnosed as Hodgkin's sarcoma by Dr. Frederic Parker, Jr., of the Mallory Institute of Pathology. In addition, the spleen and bone marrow showed an infiltration of cells without the formation of tumor nodules.

In retrospect one cannot be certain of the cause of this patient's episode which simulated acute nephritis. She did have multiple renal calculi on the right, and both ureters and renal arteries and veins were imbedded in tumor tissue. The kidneys themselves showed practically no infiltration with tumor, though they had received x-ray treatments, followed by a temporary improvement of renal function. The most likely explanation seems to be impairment of renal function through mechanical obstruction of the ureters and renal blood vessels by extrarenal tumor, but renal calculi on the right may also have been a contributory factor. In summary, this patient with acute leukemia had an episode simulating acute nephritis with edema, hypertension, convulsions and nitrogen retention, which subsided following x-ray therapy to the kidneys. At autopsy she was found to have multiple renal calculi, and both ureters and renal arteries and veins were imbedded in tumor tissue that was diagnosed as Hodgkin's sarcoma.

CASE 3. S. C. (C.H. 9068),* a 68-year-old woman, came under medical observation in October, 1941, because of increasing dyspnea, fatigability, weakness and weight loss of 1 year's duration. She was found to have signs suggestive of early cardiac decompensation and was put to bed and digitalized. She soon became nauseated, so that the digitalis was stopped. Two weeks after being put to bed she developed phlebitis, which gradually spread in the next 5 weeks to involve both legs from groin to ankle. Her appetite was poor; she felt weak, became increasingly pale and ran a daily temperature of about 100°F. A specimen of urine showed a large amount of albumin, but in a second one examined several weeks later

the albumin was within normal limits. The patient had no cough or dyspnea while lying in bed, but because of her rapid downhill course with increasing pallor and weakness she was sent to the Cambridge Hospital.

On admission, 7 weeks after her first visit to a physician, the patient presented a picture of marked pallor and debility. The heart was enlarged, the apex impulse being in the anterior axillary line. There were occasional premature beats, and a systolic murmur was heard all over the precordium. The heart rate was 100, and the blood pressure 130/40. The lungs showed dullness at the left base, with bronchial breath sounds and coarse rales. The liver was felt one fingerbreadth below the costal margin, and the tip of the spleen was felt 1 cm. below the left costal margin. There was gross edema of the left leg from the groin to the toes, with induration and tenderness in the popliteal space. The right leg was slightly swollen above the knee and considerably swollen below it.

The red-cell count was 2,560,000 and the hemoglobin 42 per cent (Sahli). The white-cell count was 409,600, with 32 per cent polymorphonuclear leukocytes, 14 per cent band forms, 2 per cent lymphocytes, 34 per cent myelocytes, 12 per cent metamyelocytes, 4 per cent basophils and 3 per cent myeloblasts. The urine was yellow and cloudy, with a specific gravity of 1.006, a very slight trace of albumin and no sugar. The sediment contained from 10 to 20 white cells per high-power field and numerous hyaline casts. The blood nonprotein nitrogen was 250 mg. per 100 cc. A blood Hinton test was negative. X-ray examination of the chest showed a small amount of fluid and some pneumonia at the left base. A second white-cell count the day after admission was 590,000. The patient had increasing dyspnea for 3 days and died suddenly on the 4th day.

Autopsy. In addition to the usual findings in myeloid leukemia, there was thrombosis of both femoral and iliac veins, as well as multiple small pulmonary emboli. There was a small patch of bronchopneumonia. The heart weighed 290 gm., and showed mild arteriosclerosis and arteriolar sclerosis and a small mural thrombus in the apex of the right ventricle. The kidneys were of considerable interest in view of the high nonprotein nitrogen (250 mg. per 100 cc.) 3 days before death. They weighed 160 gm. each and were grossly normal. There were no stones in the pelvis or ureters. Microscopic examination, however, showed considerable arteriosclerosis of the renal arteries and arterioles, and almost complete stasis throughout the vascular channels, beginning in the glomeruli, continuing in the intertubular capillary system and being most obvious in the large, dilated veins. Most of the glomeruli were intact, and the capsules were not thickened. Many showed dilatation of the afferent arterioles and of the glomerular-tuft capillaries, which were distended with blood cells, mostly primitive white cells, some of which were undergoing mitosis. There were foci of leukemic cells within the interstitial tissue, especially around the large veins, but they apparently played little or no role in mechanical obstruction of the tubules. It was thought that the uremia could be explained on the basis of a failing circulation with stasis and obstruction of the glomerular capillaries.

In brief, this elderly woman with leukemia, thrombophlebitis of both iliac and femoral veins and multiple small pulmonary infarcts died in uremia. Her renal insufficiency was due in part to circula-

*Reported through the courtesy of Dr. Gordon A. Saunders, of Arlington.

tory failure and anemia and in part to blocking of the glomerular capillaries with leukemic cells

SUMMARY

Attention is once again called to the frequency of renal failure in leukemia. The causes of this complication are nephrolithiasis, infiltrative leukemic lesions of the kidneys, obstruction of renal blood vessels or ureters by leukemic tissue, or finally nonleukemic degenerative lesions of the kidneys. The rare occurrence of gout in cases of leukemia is noted. Three cases exemplifying these complications are reported.

It is hoped that knowledge of these complications may occasionally be of help in planning the treatment of this incurable disease.

BRIEF ABSTRACTS OF THE OTHER CASES AT THE PONDVILLE HOSPITAL

CASE 4 E M S (PH 11306, previously reported in detail⁸), a 65 year old woman, who had had a mass in the left upper quadrant of the abdomen for several years, a mass in the left breast for 8 years, and had recently lost 75 pounds, was found to have a small hard, nodular, ulcerated mass in the left breast, a palpable hard lymph node in the left axilla and an enormously enlarged spleen. The blood picture was characteristic of chronic myeloid leukemia, with a white-cell count of 380,000 and a blood nonprotein nitrogen of 65 mg per 100 cc. The urine showed a specific gravity of 1.016 and a trace of albumin, with red and white cells in the sediment.

Following x-ray therapy the white-cell count dropped to 25,100, but the patient died in uremia with a nonprotein nitrogen of 188 mg per 100 cc.

Autopsy showed chronic myeloid leukemia and carcinoma of the left breast with axillary metastases. The kidneys showed some grayish white, inspissated material in the right pelvis and microscopically there were foci of lymphocytic infiltration hyalinized glomeruli atrophied tubules and subintimal thickening in the large blood vessels. In the pelvic fat in one section there was a mass of loose connective tissue in which were collections of leukemic cells.

CASE 5 W C (PH 12612), a 71 year old man was admitted because of loss of appetite a weight loss of 75 pounds and diarrhea of 3 months duration. There had been an eruption on the back of both hands for 6 weeks. On examination he was found to have skin lesions on the backs of both hands and of the right forearm consistent with pellagra. There were large masses of soft lymph nodes in both axillae and inguinal regions and an enormously enlarged spleen. The blood showed the characteristic picture of chronic lymphatic leukemia. The white cell count was 199,000 with 97 per cent lymphocytes and the red cell count was 1,730,000 with a hemoglobin of 37 per cent (Sahli). The nonprotein nitrogen was 31 mg per 100 cc and the urine sediment showed red and white cells and occasional hyaline casts.

X-ray treatment was given to the spleen with a drop in the white cell count to 112,600 but without much clinical benefit. Six months later because of increasing dyspnea and weakness the patient was readmitted and died 8 days later. Shortly before death the white cell count was 167,000, with 95 per cent small lymphocytes, and the red cell count was 1,400,000, with a hemoglobin of 75 mg (Sahli).

Autopsy revealed the usual findings of chronic lymphatic leukemia. The kidneys showed gross and microscopic scattered areas of tumor infiltration.

CASE 6 A McD (PH 12941, previously reported in detail⁹), a 56 year old man was admitted with a history of increasing weakness, pallor and a weight loss of 30 pounds in 3 years. He was found to have an enormously enlarged spleen and the blood findings were those of chronic myeloid leukemia, with a white cell count of 237,500, a red cell count of 2,940,000 and a hemoglobin of 54 per cent (Sahli). A phenolsulfonphthalein test showed 15 per cent excretion in the 1st hour and 15 per cent in the 2nd.

X-ray treatments were given to the spleen from time to time during the next 21 months, with considerable benefit. On the 4th hospital admission the spleen was enormously enlarged, the white cell count was 210,000, and the hemoglobin was 60 per cent. The blood nonprotein was 47 mg per 100 cc. Following x-ray treatment the white-cell count fell steadily to 3800 in 1 month. The blood nonprotein nitrogen, however, rose steadily to 244 mg and the patient died in uremia.

Autopsy showed the usual findings of chronic myeloid leukemia. The kidneys were of particular interest. Both contained multiple uric acid and urate calculi in the calyces, and the upper portion of the ureter was packed with gravel. Sections from the right kidney showed evidence of an active pyelonephritis.

CASE 7 H S E (PH 15613), a 54 year old man, was admitted because of enlarged painless lymph nodes of 1 year's duration. He was found to have tremendously enlarged cervical supraclavicular axillary and inguinal nodes. The liver and spleen were not felt. X-ray films

showed enlarged mediastinal nodes. The white-cell count was 3000, with 50 per cent polymorphonuclear leukocytes, 49 per cent lymphocytes, 2 per cent monocytes and 1 per cent eosinophils, but with a later lymphocyte percentage of 80 when the total cell count was 3400. The red-cell count was 3,110,000, with a hemoglobin of 52 per cent (Sahli). The nonprotein nitrogen was 52 mg., and the blood uric acid 8 mg. per 100 cc. A phenolsulfonephthalein test showed 45 per cent excretion in 2 hours, and the basal metabolic rate was +80 per cent. The urine showed a slight trace of albumin, and the sediment contained a few finely granular and coarsely granular casts and 10 white cells per high-power field.

X-ray therapy was given to both kidneys and to the right side of the neck. The nonprotein nitrogen dropped to 39 mg. and the blood uric acid to 4 mg. per 100 cc. The white-cell count dropped to 1800, with 60 per cent lymphocytes. The patient continued to feel well, but because of his leukopenia he was transfused. The next day he developed pulmonary edema and died.

Autopsy showed the changes of chronic lymphatic leukemia and of septicemia. The kidneys contained numerous small foci of lymphocytes scattered irregularly throughout, although slightly commoner in the cortex. There were no stones.

CASE 8. F. S. (P.H. 16077), a 37-year-old man, was admitted because of multiple hemorrhagic tumors of the skin of 9 weeks' duration. He had lost between 15 and 20 pounds in weight and had rapidly become worse in spite of x-ray treatment. The entire body had a purplish-red hue. Scattered over the neck, chest and all four extremities were numerous purplish-red, hemorrhagic, soft tumor nodules, imbedded in the skin and freely movable over the underlying structures. These varied in diameter from 1 to 8 cm. There were firm, enlarged lymph nodes in the neck, axillas and groins, which were matted together. There was marked edema of both legs, the abdominal wall, penis and scrotum. Almost the entire skin of the body appeared to be infiltrated with tumor and had a thick, leathery feeling. Many places were ulcerated and weeping. There was a marked gingivitis involving both upper and lower gums, which appeared hyperplastic and hemorrhagic. There were many large and small submucosal hemorrhages. The spleen and liver could not be felt. The white-cell count was 10,400, with 66 per cent polymorphonuclear leukocytes, 29 per cent lymphocytes, 4 per cent monocytes, 1 per cent myelocytes and 2 per cent nucleated red cells. The red-cell count was 2,250,000, with a hemoglobin of 35 per cent (Sahli). Three days later the white-cell count was 5900, with 79 per cent polymorphonuclear leukocytes, 20 per cent lymphocytes, 1 per cent myelocytes and 7 per cent nucleated red cells. The nonprotein nitrogen was 53 mg. per 100 cc. on entry but rose to 111 mg. 2 days later. The urine showed only the slightest possible trace of albumin, and the sediment contained 17 red cells and 1 white cell per high-power field. The patient went rapidly downhill and died 5 days after admission.

Autopsy showed extensive infiltration of practically every organ of the body with lymphoblasts. The kidneys showed heavy subcapsular, periglomerular and perivascular tumor-cell infiltration involving a large proportion of the cortical areas but almost absent in the medullas.

CASE 9. M. J. (P.H. 16198), a 71-year-old man, was admitted because of generalized lymphadenopathy, hepatomegaly and splenomegaly of 1 month's duration. He was semicomatose on admission and died 5 days later. On admission the nonprotein nitrogen was 102 mg. per cc. and the urine essentially normal. The white-cell count was 18,300, with 78 per cent polymorphonuclear leukocytes, 3 per cent lymphocytes, 5 per cent monocytes, 8 per cent metamyelocytes, 2 per cent hemohistioblasts and 4 per cent hemocytoblasts. The red-cell count was 4,180,000 with a hemoglobin of 83 per cent (Sahli).

Autopsy showed an acute stem-cell leukemia. The kidneys showed minute foci of as well as diffuse infiltration with tumor cells, most marked in the cortices.

CASE 10. E. G. (P.H. 16952), a 76-year-old woman, was admitted because of vaginal bleeding for 2 weeks. She was found to have an extensive carcinoma of the cervix. Blood studies, however, also showed the presence of acute myeloid leukemia. The white-cell count was 99,700 with 1 per cent polymorphonuclear leukocytes, 1 per cent lymphocytes, 2 per cent myelocytes, 1 per cent promyelocytes, 87 per cent myeloblasts and 8 per cent hemocytoblasts. The red-cell count was 2,500,000, with a hemoglobin of 50 per cent (Sahli). The blood nonprotein nitrogen was 32 mg. per 100 cc. The urine showed a moderate amount of albumin, and the sediment contained 15 red cells and 50 white cells per high-power field. In spite of x-ray treatment the patient died 23 days after admission.

Autopsy showed advanced carcinoma of the cervix with extension to the vaginal wall and broad ligaments, metastatic involvement of the right parailiac and para-aortic lymph nodes and metastases to the lungs. There were also the characteristic changes of acute myeloid leukemia. The kidneys showed a generalized intracapsular and perivascular infiltration with leukemic cells, as well as a patchy infiltration of the interstitial tissues, most marked in the cortices and in the peripelvic fat.

CASE 11. J. H. G. (P.H. 17640), a 75-year-old man, was admitted because of vomiting of 12 weeks' duration. He had received x-ray therapy at another hospital because of a blood picture of lymphatic leukemia. There were scattered petechiae under the tongue and in the skin over the chest. The spleen and liver were both considerably enlarged. There were no significantly enlarged peripheral lymph nodes. The white-cell count was 9400, with 26 per cent polymorphonuclear leukocytes, 6 per cent lymphocytes and 68 per cent lymphoblasts. The red-cell count was 9400, with a hemoglobin of 25 per cent (Sahli). The blood nonprotein nitrogen was 61 mg., and the blood uric acid 7.1 mg. per 100 cc. The urine contained a very slight trace of albumin, with 5 red cells per high-power field in the sediment. The patient became rapidly weaker, had bloody and tarry stools and developed additional cutaneous hemorrhages. He died 23 days after admission.

Autopsy showed the characteristic findings of lymphatic leukemia. In the left kidney there were several small calculi in the calyces, and there was a large stone in the upper portion of the left ureter. Microscopic examination showed several small scars of old infarcts and a few foci of tumor cells, but the latter were most numerous in the peripelvic fat.

RENAL HYPERTENSION

A Review of Its Status, Including the Report of a Case of
Hypertension Relieved after NephrectomyLIEUT BENJAMIN V. WHITE (MC), USNR,* RALPH E. DURKEE, MD,[†] AND
CHARLES MIRABILE, MD[‡]

HARTFORD, CONNECTICUT

SINCE Goldblatt's¹ publication in 1934, there has been widespread interest in the relation of the kidneys to hypertension. This has been manifested by reports of occasional crises of hypertension associated with unilateral renal disease in which the blood pressure was lowered following the removal of the offending kidney. The number of such reports has not been great, but some of the cases are so clear that there is no doubt of their validity.²⁻¹⁵ There have also appeared several surveys of large numbers of hypertensive patients in which attempts have been made to classify the etiology of the disease. Although these reports have shown the presence of many types of renal disease in some cases of hypertension, and a higher incidence of hypertension in patients with renal disease than in those without, more precise correlations have been generally disappointing.¹⁶⁻²¹ It is the purpose of this communication to review certain data with a bearing on this subject.

EXPERIMENTAL PHYSIOLOGY

Although Tigerstedt and Bergman² in 1896 isolated a vasopressor substance of renal origin, which they named "renin," and Janeway²³ subsequently succeeded in producing occasional hypertensive dogs by renal surgery, Cash²⁴ in 1924 was the first able to produce experimental hypertension consistently. His technic included excision of renal tissue and ligation of the renal vessels. His experiments were numerous, were carefully correlated, and included tests of renal function. His conclusions were consistent with subsequent experimental surgery and study of renal extracts. The Cash preparation is symbolized in Figure 1C. Cash concluded, first, that reduction of renal tissue by excision and by ligation of the renal vessels was followed under certain circumstances and in most cases by a rise of both systolic and diastolic blood pressures and in all cases by a rise in diastolic pressure averaging 27 mm; that the required conditions were that 50 per cent of the kidney substance be removed and that the portion deprived of its circulation remain in situ; that necrosis alone

or excision of one kidney alone produced no change in blood pressure; that after hypertension reached its peak in four or five days it tended to return to normal, the rate of return being proportional to the amount of good tissue left; and that after removing 25 to 85 per cent of the renal tissue no retention of nonprotein nitrogen occurred, whereas dye excretion was impaired after 50 per cent of the kidney tissue had been removed.

Although Cash's monumental work established the framework for the subsequent understanding of the action of renal extracts, it was Goldblatt¹ who precipitated a wide interest in that study. He found that sudden clamping of both renal arteries produced marked hypertension with uremia, a condition that he compared to malignant hypertension in man (Fig 1E). Less severe bilateral clamping produced sustained elevation of blood pressure with prolonged life but no nitrogen retention and only occasional impairment of the urea clearance (Fig 1D). Gradually increased clamping, however, produced very little change in blood pressure, a finding that Goldblatt attributed to the development of collateral capsular circulation. He also showed that experimental renal hypertension is independent of the adrenal glands or of the blood concentration of guanidine, and Page²⁵ subsequently showed that it is independent of the afferent nerves of the kidney.

Other surgical methods of producing hypertension also exist. Page,^{25, 26} in attempting to find a method of preventing collateral capsular circulation, wrapped dogs' kidneys in cellophane (Fig. 1G). The animals became hypertensive. The cellophane broke down into a fibrocollagenous hull that stimulated proliferation and led to perinephritis. Harrison, Mason, Resnick and Rainey²⁷ found that bilateral clamping of the ureters generally produced hypertension with uremia (Fig. 1F), whereas bilateral nephrectomy resulted in uremia without hypertension (Fig. 1B).

The fact that certain methods (Fig. 1F and G) did not involve occlusion of blood vessels led Corcoran and Page^{28, 29} to a study of blood flow through kidneys of animals rendered hypertensive by the Goldblatt technic. If pulse pressure was reduced by partial occlusion of the renal arteries

*Assistant in medicine, Hartford Hospital (on leave of absence).

†Assistant in medicine, Hartford Hospital.

‡Assistant in urology, Hartford Hospital.

and the arterial blood pressure was experimentally increased to permit the normal volume of blood flow, hypertension still occurred. This work sug-

removal of the sound kidney resulted in increased hypertension, whereas removal of the cellophane kidney resulted in the return of the blood pressure to normal. These observations were also true of a unilateral Goldblatt kidney.³⁰

The experimental surgical procedures illustrated in Figure 1 have been interpreted as indicating that a pressor substance is mobilized in ischemic (or otherwise damaged) renal tissue. The fact that this substance can best be demonstrated after removing large amounts of normal kidney has led many investigators to the belief that normal kidney tissue elaborates a substance that inhibits this pressor reaction.*

RENAL EXTRACTS

Because of the existence of many pressor substances of nonspecific nature and the absence of any experimental evidence of their clinical importance, Tigerstedt and Bergman's isolation of renin attracted little attention until Goldblatt's¹ work, confirming Cash's earlier observations,²⁴ became widely publicized.

In 1938, Merrill, Williams and Harrison³¹ reported studies in which they established certain differences between Tigerstedt and Bergman's renin and nonspecific vasopressor substances. Page³² also studied the physiologic action of renin. He found that when it was administered to an animal over a period of time its pressor action tended to disappear, an exhaustion phenomenon that he termed "tachyphylaxis."

In 1939, Page and Helmer³³ found that renin produced no vasoconstriction when perfused with Ringer's solution through a rabbit's ear, but that vasoconstriction did occur if a proteinlike substance, called "renin-activator," derived from red blood cells or plasma, was added. Subsequently, they found that renin and renin-activator could be incubated together to yield a third substance that would produce a sharp adrenalinelike effect. To this substance they gave the name "angiotonin." They described it as a fluorescent substance whose degree of fluorescence was proportional to its pressor activity. They stated that it was heat-stable in acid solutions, and that crystalline oxalates and picrates had been formed from it. Following the work of Muñoz, Braun-Menendez, Fasciolo and Leloir,³⁴ Page and Helmer³³ suggested that renin was an enzyme, that renin-activator was a substrate, and that the end product of their reaction was angiotonin (Fig. 2).

There is evidence that in addition to pressor substances, certain inhibitors also exist. Freeman³⁵ showed that if blood was transfused from normal

FIGURE 1. *Experimental Hypertension in Animals.*

A—normal kidneys; B—bilateral nephrectomy (usually accompanied by uremia but not by hypertension); C—ligation of renal vessels, with extirpation of nonischemic renal tissue; D—moderate sudden clamping of renal arteries; E—severe sudden clamping of renal arteries; F—obstruction of both ureters; G—cellophane perinephritis.

Hypertension occurs in all these preparations except A and B. In E and F the hypertension is associated with uremia. Preparation H represents a unilateral cellophane kidney. In this, there occurs only a moderate degree of hypertension, which is accentuated if the normal kidney is removed, and disappears if the cellophane kidney is removed. Note that in all instances the injured renal tissue remains in situ. Preparations C and H illustrate the protective influence of normal kidney substance.

gested that some factor other than ischemia per se was responsible for hypertension.

Where hypertension resulted from a unilateral cellophane kidney (Fig. 1H), Page showed that

*An alternative explanation for the protective influence of normal renal tissue is that it excretes the pressor substance. This view is apparently held by most members of the South American group.

dogs to dogs rendered hypertensive by the Goldblatt technic, a fall in blood pressure lasting from six to thirty-one minutes would occur. This sustained fall did not occur when hypertensive dogs were transfused with hypertensive dogs' blood or when normal dogs were transfused with normal dogs' blood.

Page and Helmer³⁶ considered that tachyphylaxis, or the diminishing effect of renin administered intravenously, was explained by two mecha-

FIGURE 2 The North American Concept of the Vasopressor Mechanism

Renin is a substance mobilized by injured renal tissue. It reacts with renin activator (a normal constituent of plasma) to produce angiotensin, which has a sharp, adrenalin like effect. Page has produced evidence that the angiotensin then reacts with another constituent of plasma, angiotensin activator, to yield a final vasopressor substance. Inhibitors are not clearly differentiated into those that act on renin and on angiotensin respectively.

South American workers, using different terminology, substantiate the formation of a stable vasopressor substance (presumably angiotensin) from renin and a constituent of plasma. Their evidence suggests that it is the final vasopressor substance. The South American group has found an enzyme that breaks down their substance, but no specific inhibitors.

nisms—first, the exhaustion of the supply of renin activator and, second, the presence of so-called "renin-inhibitor." Tachyphylaxis was found to occur to a lesser extent with angiotensin, and angiotensin activator was found to be present in an acetone soluble fraction of blood. These workers therefore concluded that angiotensin was probably an intermediary substance and not the final pressor agent. They were unable to differentiate the inhibitory substances in their actions on renin and angiotensin, respectively (Fig. 2). It is generally believed that renin is a substance abnormally liberated as the result of renal injury and that renin activator and angiotensin activator are normal constituents of blood.

Work similar to that of Page and his co-workers was carried out independently in Buenos Aires. Muñoz, Braun-Menendez, Fasciolo and Leloir^{34, 37, 38} showed that renin had the properties of an enzyme and that the blood globulin factor was a substrate. By incubation *in vitro* they found that these two substances formed a third

substance with the same physiologic characteristics as a vasoconstrictor substance isolated from the venous blood of ischemic kidneys. This third substance, probably identical with angiotensin, they called "hypertensin." The South American group also found that the enzymatic formation of hypertensin was limited by another enzyme that they called "hypertensinase." This substance was found to be present in extracts of many body tissues, especially plasma, liver and spleen.

Hypertensin was shown by these workers, and also by Dexter,^{39, 40} to produce no tachyphylaxis when injected into intact animals—although it did so in the isolated rabbit's ear. It is probable, therefore, that the hypothesis of an angiotensin-activator and a final vasopressor substance may eventually be discarded.

INHIBITORY SUBSTANCES

Regarding the nature of possible inhibitory substances there is a wide divergence of opinion. Page⁴¹ found that bilateral nephrectomy increased the pressor response to renin and angiotensin and greatly increased the amounts of these substances needed to produce tachyphylaxis. He concluded, therefore, that in nephrectomized animals the inhibitory substances are not present, and conversely that inhibitors are present in the kidneys of normal animals. Harrison⁴² also found that certain pressor substances were more effective in nephrectomized than in normal animals, and concluded that inhibitors exist in normal kidney tissue. The presence of such inhibitors was also suggested by the rise in blood pressure that followed the removal of the normal mate to an ischemic kidney. Conclusions based on increased vasoconstriction in uremic animals must be recognized as open to doubt because of the great vascular sensitivity of such preparations and the confused biochemical balance produced by the retention of metabolites. There is evidence, however, that certain substances capable of neutralizing the action of renin or angiotensin in animals do exist. This problem is now being attacked on the basis of three different concepts, as follows:

(1) The members of the Buenos Aires group are unconvinced of the existence of any specific inhibitor of renal origin. They have produced evidence for the existence of an enzyme, widely disseminated through body tissues, which is capable of destroying the circulating vasopressor substance (hypertensin). Recently Schroeder, Stock and Dobriner,⁴³ in this country, have demonstrated the effectiveness of aminoxidase isolated from liver tissue in inhibiting the action of a vasopressor substance (presumably angiotensin) in rats. It is probable that hypertensin and an-

giotonin are identical. It is possible that aminoxidase, or some related substance, is the hypertensinase of the South American workers.

(2) Wakerlin and Johnson⁴⁴ have demonstrated in dogs the formation of an antibody to pig's renin. They injected this substance into hypertensive Goldblatt dogs and obtained a definite fall in blood pressure, whereas the substance has been found not to lower the blood pressure of normal animals. It is unfortunate that the titer of antibody has in some cases been shown not to parallel the blood-pressure response.⁴⁰

(3) Other American workers have been engaged in the study of specific inhibitors of renal origin. Page and his associates⁴⁵ isolated a substance with which they treated a large number of patients. Although definite reduction in blood pressure usually resulted, the greatest effect was noticed when a febrile or local tissue reaction occurred. The possibility of a nonspecific foreign-protein effect cannot be entirely dismissed. Grollman, Williams and Harrison⁴⁶⁻⁴⁸ have also been working in this field and have demonstrated the blood-pressure-lowering effect of extracts of renal substance on hypertension in rats, dogs and human beings. They have recently further fractionated their extract⁴⁹ so as to eliminate the nonspecific action of concentrated salt, an error to which their earlier experiments were possibly subject. Although the new extract has been used only in rats, it appears to be specific in its effect. It requires 200 to 300 gm. of kidney to prepare one day's dose for a rat.

RENAL HYPERTENSION IN MAN

Although the renin mechanism in animals has been firmly established, direct evidence of its existence in man depends on perfusion experiments through isolated organs, a technic that is open to many nonspecific results. Many of the clinical reports of cases of human hypertension cured by nephrectomy are not entirely convincing. The following case history is unique in that the patient was followed for two years with normal blood pressure before the development of his illness and for one full year after nephrectomy.

CASE REPORT

A 39-year-old, married automobile service agent was first seen by one of us (R. E. D.) on September 17, 1933, because of recurrent episodes of low-back pain and vague abdominal discomfort, characterized chiefly by distention, pain in the right lower quadrant of the abdomen and constipation over a period of 6 years. The past history was irrelevant except for rather frequent prolonged sore throats. There were occasional frontal headaches, but no dizziness, throbbing or tinnitus, and no symptoms referable to the urinary tract. The height was 66 inches,

the weight 171 pounds, the pulse 88, the temperature 99°F., the hemoglobin 88 per cent (Dare), and the blood pressure 128/82.

Physical examination revealed a well-developed and moderately obese, healthy-appearing male. Examination of the eyes and ears was normal. The nasal septum was deviated slightly to the left. The tonsils were red, swollen and ragged, and yielded purulent material on pressure. There was no submental, cervical, axillary or inguinal adenopathy. The heart was normal in size, with regular rhythm and no murmurs or thrills. The lungs were clear throughout, the abdomen soft to palpation, and the genitalia normal. The extremities and tendon reflexes were normal. A specimen of urine was clear, concentrated to a specific gravity of 1.024, was acid in reaction (pH 4.5) and contained no albumin or sugar; the sediment was normal. Blood Wassermann and Kahn tests were negative. The patient was given advice concerning the proper care of his intestinal tract and was told to have his tonsils removed when the infection in them had subsided.

In August, 1939, the chronically infected tonsils were removed. Six days after the operation, consolidative inflammatory changes developed in both lung fields, and the patient was hospitalized for 1 month. During the following year the patient was seen on several occasions for minor complaints, at which times the blood pressure was routinely recorded (Fig. 3).

On December 7, 1940, after an interval of 6 months during which he had not been seen, the patient again reported because of almost constant, pounding headaches and dizziness. There was also an intensification of the backache noted at the first interview. The physical examination was similar to that already recorded except that the tonsils were absent and the blood pressure was 170/100. The urine showed a specific gravity of 1.020, was acid (pH 5.5) and contained no albumin or sugar; the presence of an occasional red cell was suspected. Because of the patient's urgent request for relief of symptoms, he was given potassium thiocyanate (300 mg. daily) and phenobarbital (8 mg. four times daily). This brought marked symptomatic relief and was therefore continued throughout the ensuing period of observation and investigation, though it probably affected subsequent blood-pressure readings.

During the following month investigation was undertaken while the patient was ambulatory. A complete examination of the back by an orthopedist showed no abnormalities, but the following day the patient reported lameness in the right kidney region as a result. A neurosurgeon was also consulted, who observed slight but definite changes in the caliber of the retinal vessels, but found the neurologic examination entirely normal. Roentgenographic examinations of the back and the skull were normal. Urine examination was negative except for the presence of a faint trace of albumin. A phenolsulfonphthalein test of renal function showed 25 per cent dye excretion in 15 minutes and 55 per cent in 1 hour. An intravenous pyelogram showed normal excretion from the left kidney but none from the right. Cystoscopy was therefore performed by one of us (C. M.). Retrograde pyelograms revealed a large right hydronephrosis with apparent constriction of the right ureter near the ureteropelvic junction (Fig. 4). Multiple stone shadows were visible at the lower pole of this kidney. Urine from both ureters was sterile, and contained 0 to 5 red cells, 0 to 3

smooth muscle. After removal of the kidney the blood pressure returned to normal. This case is a human example of the principle involved in the application of Goldblatt's clamp. The case reported by us had almost complete obstruction of the right ureter. The combination of obstruction and limitation of elasticity in the capsule may well have contributed to limited vascular pulsations in this case.

The uncommon occurrence of cases of hypertension due to unilateral renal disease does not necessarily indicate that the mechanisms outlined occur with equal rarity. If there are proved unilateral cases, presumably there are bilateral cases that cannot be proved by nephrectomy. In view of the fact that there is less normal renal tissue to exert its protective effect, such cases may outnumber the unilateral ones.

It would be premature to draw conclusions about the etiology of essential hypertension. It is probable that the number of human cases of renal hypertension is larger than the sporadic reports of proved unilateral disease indicate.

SUMMARY

The experimental basis of renal hypertension is discussed. The renin mechanism in animals appears to be definitely established. There are isolated instances of renal hypertension in man. These cases may be due to the renin mechanism.

A case of unilateral renal disease with hypertension is reported. The blood pressure was followed for two years before the onset of hypertension and for one year after recovery, which was instituted by removal of the diseased organ. The specimen was unusual in that there was an extensive granulating perinephritis in addition to an almost completely occluded ureter.

MEDICAL PROGRESS

THE MECHANISM OF HEART FAILURE AND RELATED STATES*

LAURENCE B. ELLIS, M.D.†

BOSTON

ALTHOUGH heart disease and heart failure are among the commonest and most serious conditions that afflict mankind, the average doctor is inclined to accept empirically the symptoms and signs that occur, and makes little attempt to relate them to the actual physiologic disturbances of the circulation. This attitude is taken in spite of the fact that the heart and blood vessels constitute a physical system in which vital biologic processes are less important than in the functioning of many other organs. In recent years an impressive accumulation of experimental evidence has added to knowledge in this field, and has permitted cardiologists to buttress some of their theories and to discard others.

The lag in general understanding of the mechanism of circulatory failure is due in part to the highly specialized nature of many of the experimental methods employed; in part to the complicated theoretical considerations involved; and in large part, too, to the fact that many physicians, and even cardiologists, have in the past considered the heart to be an isolated organ and have not paid proper attention to the fact that the heart and the peripheral blood vessels are integral parts of the same system, and that manifestations of heart failure are to a large extent demonstrable only in the peripheral circulation. There is now enough clinical and experimental evidence so that all physicians should have at least a working knowledge of the dynamics of the circulation in heart disease and of the nature of circulatory failure; if they so relate the clinical findings exhibited by their patients they will be better doctors, for their interpretations of signs and symptoms will rest on a sound basis.

So much has been published in this field of medicine in the last few years that it is undesirable to cite a comprehensive series of references. Specific articles will be referred to only when they have appeared recently, and no attempt will be made to cover the field completely. Papers are cited which

will add to the understanding of the general practitioner concerning certain manifestations of heart disease and failure.

Mechanism of Congestive Heart Failure

Two outstanding theories have been advanced to explain the physiologic mechanism of congestive heart failure. One, the "forward-failure theory," holds that the manifestations of cardiac decompensation are caused in the main by an inadequate output of blood by the heart. This was the belief of Sir James Mackenzie and Sir Thomas Lewis, and represents the point of view maintained until recently by most English and American clinicians. The second, the "backward-failure theory" of heart failure, was first clearly expressed a hundred years ago by James Hope. In the simplest terms it attributes the phenomena of congestive failure to congestion in the vascular circuit behind the failing ventricle. This theory has been accepted by most French and German clinicians ever since Hope's day, and in the last few years has been increasingly adopted by American investigators.

The forward-failure theory is attractive because of its apparent simplicity. The heart being a pump, it might appear at first glance that heart failure consists merely of a failure of this pump to eject sufficient blood. It is now possible to test this explanation experimentally, since in recent years technics have been perfected that are accurate in estimating the cardiac output under various conditions, and many data are now available. No attempt will be made to describe or evaluate these methods, all of which have their limitations, but the results obtained through them are now sufficiently numerous and in close enough agreement to justify certain conclusions.

As regards the relation between cardiac output and heart failure, Harrison¹ concludes, "Persons with congestive heart failure may and often do have diminished circulatory minute volume, but this is not the essential cause of their symptoms." Others have taken issue with this statement. Altshule² believes that the fundamental defect in congestive failure is a cardiac output that is low in relation to the metabolic needs of the body and the venous pressure. With this viewpoint Stewart³ agrees. Subsequent to the publication of these monographs, McGuire and his co-workers⁴ dem-

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual, Vol. III, 1942* (Springfield, Illinois: Charles C Thomas Company, 1942. \$5.00).

onstrated low cardiac outputs in 3 patients in heart failure with an increase during recovery, but in a fourth patient the more severe the failure, the higher was the output. In another study they⁵ found low volume flows in 19 of 20 decompensated patients. The same authors⁶ also presented evidence, that patients with congestive failure are unable to increase their cardiac output in response to exercise to an extent that is attained by normal persons. Espersen⁷ has reported finding normal cardiac outputs in 12 of 27 patients in heart failure, although Seymour et al.⁸ obtained low outputs during failure in all the 6 patients studied, and the outputs increased with clinical improvement. Starr,⁹ employing an entirely different technic, that of the ballistocardiograph, has presented results indicating that heart failure may occur with normal or even supernormal circulation. The validity of this method has not yet been fully demonstrated, but the results are certainly suggestive. It is also well known that heart failure may occur in conditions characterized by increased circulation (hyperthyroidism, arteriovenous aneurism, anemia and possibly beriberi). It would seem wisest, therefore, in the light of our present knowledge to echo what Starr says:

The majority of cases [of congestive failure] have subnormal circulations, and improvement in the circulation often coincides with clinical improvement. On the other hand, the relationship is not invariable, and any idea that the symptoms are the direct mechanical consequence of a diminished circulation must be abandoned.

In summary, therefore, our present knowledge suggests that the relation of cardiac output to heart disease and failure is as follows:

In compensated organic heart disease the resting cardiac output is often somewhat reduced, but may be normal or even increased.

In congestive heart failure there is usually a further decrease in cardiac output. The output per beat is especially apt to be impaired. When the output is considered in relation to the oxygen consumption of the body (basal metabolic rate) or to the venous pressure of blood reaching the heart, its diminution is even more evident. Nevertheless, the output is occasionally normal or even increased, either in absolute terms or relatively to the output before failure occurred. The degree of clinical failure does not bear any quantitative relation to the change in output.

With recovery from failure the output usually improves, but rarely to the point that existed before failure.

In the presence of heart disease, exercise increases the cardiac output less than normally;

and if congestive failure is present, the increase in flow is even smaller.

The cardiac output may be reduced in many conditions—acute or chronic—in which none of the signs of clinical heart failure are present.

A simple decrease in cardiac output is an inadequate explanation of congestive heart failure.

If, then, the clinical picture of congestive failure cannot be adequately explained by decreased cardiac output alone, what is the causative mechanism? The answer is to be found, not in the outflow of blood from the heart, but in the inflow into the auricles and ventricles. Twenty to thirty years ago, Starling and his associates^{10,11} carried out a brilliant series of investigations on cardiac physiology, and found that an increase in stretching—that is, dilatation—of the muscle, is accompanied by an increase in the strength of contraction; that the venous pressure is the important factor in controlling this diastolic stretching and hence the cardiac output; and that the rate of metabolic processes of the heart muscle is determined by the length of the fibers rather than by the work accomplished (that is, a dilated heart consumes relatively more oxygen than a normal one).

According to the backward-failure theory of congestive failure, the diseased heart is inefficient, requires a greater venous pressure and hence more dilatation in order to effect a given output of blood, and uses up more energy—that is, consumes more oxygen—in doing so. This results in more and more cardiac dilatation, with an increasing amount of residual blood left in the ventricles in diastole. The presence of this residual blood produces effects transmitted back to the auricles and to the great veins so that blood under increased pressure piles up in the vascular circuit,—either pulmonary or systemic,—and this congestion initiates the train of circumstances that produces the characteristic symptoms of heart failure—dyspnea, edema and so forth. Since in the vast majority of clinical types of heart disease the left ventricle is subjected to greater strain than is the right, it usually fails first, and it is the pulmonary circuit that is engorged. Eventually the strain that this vascular congestion and hypertension impose on the ventricle that has not failed proves too great, and this ventricle in turn fails.

In the controversy that has existed between the backward-failure and forward-failure exponents, one point is not infrequently overlooked which to some extent reconciles the two viewpoints. This is that blood normally must be simultaneously pumped by both ventricles in exactly equal amounts. If one ventricle ejects less than the other, even by a minute amount or for a few beats, blood

tends to pile up in the vascular circuit behind the impaired ventricle, until the venous pressure is sufficiently raised to act as a stimulus for an improved ventricular discharge. Such small and relative changes in volume flow from the two sides of the heart cannot be measured in human beings by any available method, but it is probable that they play a significant role in the pathogenesis of congestive failure, and possibly in the exertional dyspnea of persons with limited cardiac reserve.

Further consideration concerning how back pressure and congestion behind a failing ventricle can lead to clinical manifestations, together with the many secondary factors that contribute to the aggravation of the symptoms, will now be discussed.

Dyspnea

Dyspnea is the cardinal symptom of left ventricular failure and is explainable by the sequence of vascular events described above occurring in the pulmonary circuit. With dilatation of the left ventricle and increase in pressure in the pulmonary veins, there ensues an increased pressure transmitted back into the pulmonary capillaries, with resultant engorgement of these vessels and ultimate exudation of fluid into the alveolar spaces. Consequent on these changes the lungs are stiffened by the dilated, engorged vessels, the vital capacity is diminished, and the residual air is increased. It is known that the respiratory reflex that alternately initiates inspiration and expiration (Hering-Breuer reflex) is dependent on the degree of stretching or stiffening of the lung, and that in experimental animals in which sudden pulmonary vascular engorgement is produced rapid, shallow breathing results.¹² The distressful, rapid, shallow breathing that occurs in clinical heart failure is therefore due in large part to this reflex effect occasioned by the pulmonary congestion. Other factors may play a role, but probably not an important one, except in advanced heart failure or during exercise. Such factors are arterial anoxemia caused by impairment in the pulmonary exchange of gases, and central effects on the respiratory center as a result of failure of an adequate circulation in providing oxygen or removing carbon dioxide or other acid metabolic products.

The cause of paroxysmal cardiac dyspnea is not fully established, but no better explanation has been given than that of Weiss and Robb.¹³ In brief, according to their theory the cause is acute left-sided failure, precipitated by one or more trigger mechanisms, all concerned with the inadequacy of the horizontal as compared with the elevated position of the thorax. These advantages of the elevated thoracic position are mechanical factors aiding breathing, decrease in the hydrostatic element

of both peripheral and pulmonary venous pressure, and a slight and possibly inconstant decrease in cardiac output. In addition, when a cardiac patient assumes the recumbent position after having been up and around during the day, there may be a well-marked increase in plasma volume due to the mobilization of extravascular fluid. This added circulatory burden was suggested by Weiss and Robb, but it remained for Perera and Berliner¹⁴ to demonstrate it unequivocally in cardiac patients subject to paroxysmal dyspnea.

A possible role of neurogenic reflexes in the precipitation of these attacks was also brought out by Weiss and Robb. However, that such a role is contributory only is the belief of the majority of investigators.

Edema and Diuresis

Until comparatively recently the explanation of edema of cardiac origin seemed to be simple. Since there is an increased pressure in the peripheral veins in right-sided heart failure, it was logical to assume that this heightened pressure is conveyed back to the capillaries, thus increasing the hydrostatic pressure and the tendency for more fluid to be driven into the tissue spaces. Fahr and Ershler¹⁵ have shown that edema is likely to form when the hydrostatic pressure at the venous end of the capillary loop rises to within 2 mm. (mercury) of the colloid-osmotic pressure of the plasma. However, the complexity of the factors contributing to edema formation is becoming increasingly evident, as Altschule² has brought out, and he has shown that the degree of edema does not bear any absolute relation to the height of the venous pressure. Several elements enter into the control of the level of pressure in the venous system. Not only is the ability of the heart to pump forward the blood reaching it important, but peripheral conditions modify the pressure level. The degree of constriction of the blood vessels in various parts of the vascular circuit is one prominent factor. A lowered venous tone tends to lower the venous pressure; increased arterial tone with a normal venous tone tends to shunt blood into the venous channels, and hence to increase the venous pressure. The total volume of circulating blood also plays a vital role, as has been brought out by Bazett.¹⁶

It has been shown^{8, 17, 18} that the blood volume is often increased in heart failure, especially that of the chronic right-sided type. The assumption has frequently been made that this increase in plasma volume is the result of the train of circumstances consequent on a high venous pressure and an increase in the peripheral vascular bed, and that with improvement and the onset of diuresis this

train of events is reversed; that is, the venous pressure falls owing to improved cardiac action, the plasma volume decreases because of better renal activity as the result of improved renal blood flow or the effect of diuretics, and fluid returns to the blood stream from the tissues and is excreted. However, a number of recent observations do not conform to this simple explanation. Stewart¹⁹ found evidence that the plasma proteins fall with the onset of diuresis, suggesting that fluid enters the blood stream to dilute the plasma *before* diuresis commences. Swigert and Fitz²⁰ also found the plasma volume sometimes increased after giving a mercurial diuretic, as though the fluid were first mobilized from the tissue, before renal excretion took place. Calvin, Decherd and Herrmann,²¹ however, found such an increase in only 2 cases following the administration of Salyrgan, and in these patients diuresis was delayed or failed to occur. In 13 other cases where prompt diuresis took place the plasma volume diminished. Of significance, too, is the observation of Fletcher and Schroeder²² that some patients with cardiac edema apparently have a specific tendency to retain sodium and that their loss of edema fluid follows a change in the sodium balance. Warren and Stead²³ are of the belief that edema develops in congestive failure because the renal excretion of salt and water is altered by a decreased cardiac output, and that this increase in extracellular-fluid volume is accompanied by an increase in plasma volume that eventually causes a rise in venous pressure. Support for the thesis that a rise in venous pressure follows an increase in plasma volume is to be had in the work of Starr,²⁴ who showed that the pressure in the veins and other parts of the vascular circuit after death of patients dying in congestive heart failure is markedly higher than in those dying of other causes. He interpreted this as possibly due to an increased blood volume that overloads the vascular system.

It has not yet been conclusively shown in what way the venous pressure, as measured in the usual fashion in the antecubital vein, reflects the pressure in the capillaries on the one hand and in the right auricle on the other. There is evidence that normally the antecubital venous pressure is higher than that in the right auricle by several centimeters of water,²⁵ but this gradient is abolished in patients and experimental animals with right-sided heart failure and elevated venous pressure.

The explanation for these various observations, at variance with the usual concept of edema formation and diuresis, is not entirely clear, but it has been suggested by Schroeder and by Warren and Stead that hormonal influences may be involved

in the retention of electrolytes. It is well known that the hormones of many of the endocrines exert some antidiuretic effect²⁶ and that actual heart failure in patients with Addison's disease may be precipitated by an overdosage of desoxycorticosterone,²⁷⁻³⁰ owing to excessive sodium retention and increase in plasma volume.

Thus the exact relations and the causal connections between the level of venous pressure and the degree of heart failure remain unsolved problems. It is not unlikely that a vicious circle is established whereby right-sided heart failure produces vascular congestion and a tendency toward increase in pressure in the systemic venous reservoir. This in turn initiates a sequence of events that may maintain or further elevate the pressure regardless of the cardiac status itself. These other factors affecting edema formation deserve consideration.

Landis and Gibbon³¹ and Sodeman and Burch³² have pointed out the importance of tissue pressure in controlling edema formation. Persons with firm, elastic subcutaneous tissues accumulate edema much less readily than do those whose tissues have lost their elasticity and are readily stretched, such as old people and those who have lost weight or who have previously been edematous.

The role of a lowered plasma osmotic pressure in cardiac edema has also come in for a good deal of study, and it is now well known that the plasma proteins and especially the albumin fraction may be significantly lowered. Several factors may contribute to this lowering: impaired intake of protein; deficient absorption; increased loss through the kidneys, into serous effusion or into edema fluid itself; defective formation due to hepatic congestion; and hydremia or increase in plasma volume without a concomitant increase in plasma protein. The lower the plasma osmotic pressure from whatever cause, the less the increase in hydrostatic pressure that is required to initiate edema formation.

Another factor that may play a part in edema formation is capillary anoxemia, which causes dilatation and increased permeability of the capillaries. Smirk's³³ experiments indicate that such anoxemia is important in the production of cardiac edema, but Fahr and Ersler¹⁸ are of the opinion that it plays little or no part. The fact that the protein content of cardiac edema fluid is low, averaging less than 0.5 per cent, indicates that increase in capillary permeability does not progress to a point permitting the passage of protein in high concentration.

Lymphatic drainage from the
has been shown to occur in patients with

CASE 29091

PRESENTATION OF CASE

A twelve year old boy was referred to this hospital with a diagnosis of pneumonia.

Three days prior to admission the patient complained of epigastric pain and on the next day ate poorly and did not seem well. However, there were no other signs or symptoms. On the day prior to admission he vomited ingested food and his temperature was elevated to 103°F. His physician found signs of consolidation in the right lung, and because of fever, 2 gm. of a sulfonamide drug was administered. On the day of admission he developed a hacking nonproductive cough. At no time had he experienced chills.

The family history was noncontributory. For three and a half years the boy suffered with repeated attacks of otitis media and mastoiditis necessitating bilateral drainage of the middle ear and resection of the mastoid cells on the left side. Three years before entry, because of a suspected brain abscess, an exploration was made through the right temporal bone; no abscess was found. Six months previously, because of recurrent pain in the left mastoid area and profuse drainage of pus from the ear, mastoid resection was revised. He was treated with a course of orally administered sulfadiazine totaling 46 gm. in nineteen days. *Staphylococcus aureus* and a beta hemolytic streptococcus were cultured from the pus.

Physical examination revealed an acutely ill, cyanotic, obese boy. Respirations were rapid and shallow, and there was an occasional hacking nonproductive cough. The mucous membranes were congested and dry. The heart was normal. The right chest was dull from the midscapula to the base. Bronchial breathing and bronchophony were prominent throughout the right chest posteriorly in the axilla and to a less marked degree anteriorly at the base. The abdomen was soft, and no masses were felt.

The blood pressure was 110 systolic, 70 diastolic. The temperature was 105°F, the pulse 90, and the respirations 60.

The white cell count was 26,000. The urine was acid, had a specific gravity of 1.015 and gave a +++ test for albumin; the sediment contained an occasional white cell, an occasional red cell and many hyaline and granular casts.

A chest roentgenogram taken in the horizontal position showed increased density throughout the greater portion of the right lung field more marked in the medial two thirds of the lung. The density had a ground glass appearance and was more marked at the base. The heart was slightly displaced to the left. The left lung was not remarkable. No pyothorax were grown from the sputum, and only obvious contaminants were found in the blood culture.

Despite the intravenous administration of 10 gm. of sodium sulfadiazine during the first day, producing a blood level of 15.6 mg. per 100 cc, the boy became increasingly restless and disoriented. The pulse rose above 120, and he died approximately thirty hours after admission.

DIFFERENTIAL DIAGNOSIS

DR. WYMAN RICHARDSON. In the first place, I am sort of hipped on blood smears, and I should like to comment that with a white cell count of 26,000 in a boy with a temperature of 105°F, and findings in the chest, a good deal of stress might justifiably be laid on the type of blood picture. The white cell count was done in the Emergency Ward, and no differential count is given anywhere in the record. I should suspect it showed 94 per cent polymorphonuclears, 6 per cent lymphocytes, no eosinophils and no monocytes. On the other hand, because nothing is said about the differential count, perhaps we can accept it as normal—that is of great significance. I doubt if it was. I should also guess that the boy had a red cell count of 3,500,000 with a hemoglobin of 11.6 gm.

The questions I should ask in regard to this boy are: Did the previous sepsis have anything to do with the present illness? Did the boy have pneumonia? Did he have empyema? And finally, did he have amyloid disease or did he have nephritis of some type? These are the questions I have to answer, but I am not sure that I am going to be successful.

In the first place, did the previous sepsis have anything to do with the immediate illness? My inclination is to suspect a pneumonic process which had nothing to do with the previous mastoid infections. In other words, I think he did have pneumonia on the evidence here submitted. I suspect the presence of pneumonia from the history of the onset and from the physical findings. The question is, Were the physical findings

definitely those of consolidation or could they have been those of fluid and compression of the lung?

Whether he had empyema or not, I am not sure. If it was empyema, one would be surprised to find such definite evidence of it so soon in the course of the recent illness. One would have to believe he had had it for some time.

Finally, in regard to his kidneys, there was a moderate reduction in the specific gravity. There was a large amount of albumin, which is greater than I should expect with a temperature of this degree, especially when it was associated with a gravity that was somewhat low. If it were not for the granular casts I should be thinking definitely in terms of some type of nephrosis—especially amyloid disease, because of the previous sepsis. I do not see how I can rule amyloid disease out or in on the basis of this history. The questions are whether he had amyloid disease of the kidney, whether he had subacute nephritis or whether the renal damage could be attributed to a reaction from sulfadiazine, which was given six months before entry for a course of nineteen days. I have not heard of any cases of kidney disease that progressed for six months after the cessation of the use of sulfadiazine or any of the sulfa drugs. I should say he had either subacute nephritis or amyloid disease and I shall make final diagnoses of pneumonia, chronic suppurative mastoiditis and kidney disease, possibly amyloid in nature.

I have not looked at the x-ray films. Dr. Mallory intimated to me that Dr. Schatzki was particularly interested in them. I should think I might be allowed to look at the plates first, and Dr. Schatzki can discuss them afterward.

This film was taken with the patient in the horizontal position and the question comes up, Was this one of those cases of so-called "localized edema" of the lungs associated with renal disease in which Dr. Mallory thinks that there is some sort of a consolidating process? Am I wrong in saying that?

DR. TRACY B. MALLORY: I am still uncertain what that lesion really is. In such cases, the lungs usually appear more hemorrhagic than edematous.

DR. RICHARDSON: I do not know much about x-ray films, and I shall not go out on a limb on that diagnosis in this case. I want to mention it knowing that Dr. Schatzki is going to talk about these films. From this film, I cannot rule out the possibility of fluid in the right chest. The heart seems to be pushed somewhat to the left. I am going to put in a question of empyema in addition.

DR. RICHARD SCHATZKI: This case was presented to the X-ray Department from the Emergency Ward with a clear-cut diagnosis of lobar pneu-

monia. For several reasons, the dangers in the chest looked somewhat different roentgenologically from those of the common variety of lobar pneumonia. The area involved was rather large but not dense. It had a translucent, ground-glass appearance, as the record states, apparently owing to alveoli that were not yet involved by the process. The medial portions of the lung were much more involved than the peripheral one. All this made us think that it might well be a localized pulmonary edema. We could not rule out pneumonia, in addition to the pulmonary edema. We certainly thought that the kidney should be checked. This was done, resulting in the findings that are mentioned.

DR. WILLIAM B. BREED: Dr. Richardson, I suggest that the person who abstracted this record perhaps took a little too much on himself in the last paragraph when he said, "Despite the intravenous administration of 10 gm. of sodium sulfadiazine during the first day, producing a blood level of 15.6 mg. per 100 cc., the boy became increasingly restless and disoriented. I suggest that he might have said "because of." That is a high blood level, and the boy had had a large amount of sulfadiazine six months previously. I am not sure that the treatment was not a factor in his rather sudden demise.

DR. RICHARDSON: Fifteen milligrams does not seem to be an unusual level. It is frequently attained without serious toxic symptoms.

DR. ALLAN M. BUTLER: Was the 10 gm. given intravenously at one time? I think that is a lot.

DR. MALLORY: It was divided into at least two doses.

DR. BUTLER: How far apart?

DR. MALLORY: It was spread over twenty-four hours. There is no further comment.

DR. BUTLER: Before we hear the diagnosis, I should like to ask Dr. Schatzki if there is prominence of the right border of the heart at the base.

DR. SCHATZKI: No; I think it is normal considering the conditions under which the film was taken.

DR. FULLER ALBRIGHT: This boy was in the hospital about twenty-four hours. I saw him in an oxygen tent, and he was obviously extremely sick. To me, he obviously had a pneumonia. The localized edema of the lungs that Dr. Schatzki has mentioned would be most unusual. The only question in my mind was whether he had acute cardiac failure. We felt sure it was pneumonia. We did not get a differential count, which was unfortunate. It might have given a clue.

DR. BUTLER: There were many hyaline and granular casts in the urine. I do not know whether the boy was dehydrated or not.

DR. ALBRIGHT: The high fever and passive congestion could explain these. One certainly observes casts with high fever.

DR. BUTLER: Yes, but the specific gravity was only 1.015, which means the urine was not concentrated. With high fever, casts and red cells in the urine are usually associated with a concentrated urine.

DR. ALBRIGHT: That is true, but I must confess that I am not disturbed about it.

DR. MALLORY: I shall describe the anatomical findings and then ask Dr. Schatzki to speak again.

CLINICAL DIAGNOSES

Lobar pneumonia.

DR. RICHARDSON'S DIAGNOSES

Chronic suppurative mastoiditis.

Pneumonia.

Kidney disease (? amyloid).

Empyema?

ANATOMICAL DIAGNOSES

Acute glomerulonephritis.

Subacute mastoiditis.

Pulmonary edema.

Pneumonia.

Operative scar: decompression wound.

Focal encephalomalacia, old, inactive.

PATHOLOGICAL DISCUSSION

DR. MALLORY: At autopsy this boy had large, distended and heavy lungs. The peripheral portions of the lungs in all lobes were well aerated, whereas the central portions were practically consolidated, with obviously a great deal of fluid in the alveoli. The lungs did not show any granular foci. Our impression in gross was that this was a massive degree of pulmonary edema centralized in the hilar regions and not present in the peripheral portions of the lung. The kidneys were of normal size. When sectioned, the cortices seemed paler than normal and bulged a little bit over the capsule, but in gross we could not be certain of nephritis. The sections, however, show an obvious acute intracapillary glomerulonephritis. The sections of the lungs are much more difficult to interpret. They look frankly pneumonic, with a great many leukocytes and some fibrin, but also a good deal of free fluid and a great many red cells. It is well within the limit of possibility, and as a matter of fact I think it probable, that these lungs were edematous at first and became pneumonic terminally—in other words, that the pneumonia was secondary rather than primary. However, I cannot prove that on histologic grounds.

I think all of us have been impressed with the way Dr. Schatzki looks at a chest plate and often diagnoses nephritis. All of us have seen him do it too often for it to be pure coincidence. I am convinced that there is something in it. The nature of this pulmonary lesion is difficult to explain. It is different from the ordinary types of pulmonary edema that we see in other conditions. Pulmonary edema usually takes one of two forms. In one, there is an obviously wet lung. Frothy fluid bubbles from the bronchi when you press on the lungs, and pours in abundance from cut surfaces of the pulmonary parenchyma. That is what one sees with acute heart failure and with so-called "cardiac asthma." In the other type of pulmonary edema the fluid is not readily expressed by pressure. It seems to be of a gelatinous consistency, and when the lung is fixed it is precipitated as a diffuse colloidlike sheet in the alveoli rather than as granular detritus. In either type small numbers of red cells may be found in the alveoli. The lesions in the group of nephritic cases that Dr. Schatzki has been interested in do not look like those of either type of ordinary edema. The gross appearance of the lung is that of scattered hemorrhages, and microscopic examination always shows more obvious hemorrhage than edema. There is always fluid as well, but the red cells are so numerous that they predominate the picture. There is apt to be some fibrin, and there may or may not be leukocytes. In this case there were so many leukocytes that if I did not have the history, I should have passed it over as ordinary pneumonia.

A PHYSICIAN: A fatal course in twenty-four hours is extremely unusual for pneumonia. Furthermore, a pneumonia involving all five lobes is rare in the absence of a predisposing factor. What does the negative culture mean?

DR. MALLORY: I do not know. I wish we had been more impressed with the idea of pneumonia at the time of death and had cultured the lungs more carefully than we did. Certainly, the negative sputum makes me suspicious that it was not the usual pneumococcal pneumonia.

DR. SCHATZKI: The post-mortem film of the chest is interesting. It looks practically like that of a stillborn baby. There is barely any air in the lungs. The right lung has none, but there is a little in the periphery of the left lung, as you can see. It seems to me that the coincidence of these pulmonary lesions with nephritis, as Dr. Mallory points out, is too common to be laughed off. In some of these cases the films of the chest look exactly like those of cases of pulmonary edema of cardiac origin; the changes are bilateral and fairly symmetrical. In others, the pulmonary le-

sion is asymmetrical and less characteristic. The roentgenologic picture, as well as the clinical course, is not that of pneumonia.

DR. MALLORY: Would you be able to distinguish the picture from so-called "rheumatic pneumonia," Dr. Schatzki?

DR. SCHATZKI: I have not seen many cases of rheumatic pneumonitis. The films in these few cases showed changes that looked roentgenologically like those of localized pulmonary edema, and the patients acted much the same. From talking with you, Dr. Mallory, and with Dr. Bland, I have been impressed that these two conditions are also similar histologically.

DR. MALLORY: I am inclined to think that the histologic picture is the same in certain cases.

DR. FLETCHER H. COLBY: Is there any possibility that the previous sulfadiazine had anything to do with the picture?

DR. MALLORY: This was acute glomerulonephritis, and there was no sign of sulfadiazine involvement. The process was acute and had not reached a stage where the boy would have died of renal insufficiency if he had not had the pulmonary complication.

DR. RICHARDSON: Did he have fluid in the chest?

DR. MALLORY: Only 6 or 7 cc. on each side.

DR. ALBRIGHT: May I ask Dr. Schatzki a few questions? I want to be sure I understand this. In certain cases of kidney disease, is there edema in the lungs that is not due to low serum protein, not due to generalized anasarca, and not due to hypertension and cardiac failure? What is it? Can you be sure it is not caused by pneumonia?

DR. MALLORY: It might be a sterile pneumonia like the sterile pericarditis one sees in uremia. Other well-known inflammatory lesions in uremia are, of course, colitis and gastritis. This may be a pulmonary manifestation of the same type of capillary injury.

DR. ALBRIGHT: In other words this is a pneumonia for which you can find no bacteria. I cannot see why you cannot get acute pneumonitis from the same bug that is causing the trouble in the kidney; that is, the same process is going on in the lung as in the kidney.

DR. MALLORY: For one thing the streptococcus is not found in the kidney, and you do not ordinarily find streptococci in these lungs. However, the problem is difficult to solve with post-mortem studies since edema fluid is an ideal culture medium and so many organisms grow luxuriantly in it that mixed cultures are the rule and are often impossible to interpret.

DR. SCHATZKI: A few facts are difficult to fit in with your theory, Dr. Albright. A number of

these patients did not have acute glomerulonephritis, but chronic or subacute glomerulonephritis. In some of them, the pulmonary lesions developed simultaneously with generalized anasarca.

DR. ALBRIGHT: Localized edema of the lung and generalized anasarca?

DR. SCHATZKI: In addition, a number of patients showed no clinical evidence of infection. Furthermore, in several cases at autopsy the histologic picture was not that of pneumonia but that of hemorrhage.

DR. ALBRIGHT: Hemorrhagic exudate?

DR. MALLORY: Yes; it looked as if the capillaries let red cells through instead of merely fluid.

A PHYSICIAN: No white cells?

DR. MALLORY: Only a small number such as you might expect in proportion to the red cells.

DR. JOSEPH AUB: You call this "localized edema." What is the evidence of this edema?

DR. SCHATZKI: It has the roentgenologic appearance of localized edema as seen occasionally in pulmonary edema of cardiac origin. The picture is more obvious in cases with symmetrical bilateral pulmonary edema.

DR. MALLORY: Have you not had some cases with acute nephritis in which the x-ray picture cleared up with dramatic suddenness in twenty-four hours?

DR. SCHATZKI: That is right. It is rather hard to connect that with pneumonic consolidation.

DR. BUTLER: To me there is something odd about this patient, if he had acute glomerulonephritis.

DR. MALLORY: It is a frequent sequel of mastoid disease.

DR. BUTLER: Yes, but these patients do not die of uremia and acute glomerulonephritis in a course of three days.

DR. MALLORY: We are not claiming that he did, Dr. Butler.

DR. BUTLER: All right. Then if his death was due to nephritis, he ought to have had either cardiac failure with hypertension or a crisis of hypertension earlier, in the first few days of the acute process. He had diminished concentration of urine, and it seems to me that the story and findings are not consistent with death and acute hemorrhagic nephritis.

DR. MALLORY: The patient died because he could not breathe, died because of his lung condition.

DR. BUTLER: How often do you find that in the lungs without hypertension or cardiac failure or without uremia?

DR. MALLORY: One can have acute cardiac failure in nephritis without hypertension, according to Longcope.*

DR. BUTLER: Yes, but there is nothing in the physical examination to give evidence of cardiac failure.

DR. ALBRIGHT: We thought clinically that there was a possibility of cardiac failure.

CASE 29092

PRESENTATION OF CASE

A twenty-seven-year-old housewife came to the Out Patient Department of the hospital because of pain in the right lower quadrant of the abdomen.

Approximately five years prior to admission the patient noted the onset of attacks of nonradiating pain in the right lower quadrant of the abdomen. This was usually knifelike but occasionally was crampy and caused her to double up. These attacks usually lasted about an hour and were relieved by bed rest. The pain often occurred every two or three weeks but bore no apparent relation to the menstrual cycle. Simultaneous with the episodes of pain a mild leukorrhea developed, but the patient denied any exposure to venereal infection. Between attacks the patient had a constant dull ache in the right lower abdomen. There were no gastrointestinal symptoms associated with the illness. For the past several months she had had nocturia two or three times every night.

The family history was noncontributory. The patient had had a normal child eleven years previously. At about the same time her first husband died of pneumonia, and she remarried four years later. Although both she and her husband desired a child, no pregnancies had occurred.

Physical examination disclosed slight tenderness in the right lower quadrant of the abdomen, but no mass was felt. There was some thickening of the left broad ligament, and a 4-cm. tender mass was felt in the right vault that seemed connected with the fundus of the uterus. There was a slight erosion of the cervix, with a profuse vaginal discharge. A cervical smear and culture were negative for the gonococcus.

The urine was acid and had a specific gravity of 1.030; the sediment contained an occasional red cell, 7 white cells and 15 epithelial cells per high-power field.

The patient was started on sulfadiazine and warm vaginal douches, and was told to rest in bed. During the next two weeks, the discomfort gradually improved and the vaginal discharge was re-

duced. The right adnexal mass seemed to persist but was only slightly tender. After two weeks the sulfadiazine was discontinued but the patient was instructed to continue the warm vaginal douches. Several days later she had a sudden attack of crampy pain that caused her to double up. Ice packs applied to the abdomen temporarily relieved the pain but she continued to have a steady dull ache in the lower abdomen. She was then admitted to the ward.

The menarche started at fourteen and the periods were always regular, with a twenty-eight-day cycle, and lasted three days, with no pain. The last catamenia began five days before she entered the hospital.

Physical examination revealed a well-developed young woman in no obvious distress. Examination of the heart and lungs was negative. There was marked tenderness to direct pressure in the right lower quadrant of the abdomen. No rebound tenderness could be elicited, and no masses were felt. On vaginal examination there were definite tenderness and thickening in the right vault. One examiner described a moderately tender right adnexal mass about the size of a small orange. The cervix was lacerated and seemed soft. The uterus was slightly enlarged and was freely movable. A small amount of white discharge was present in the vagina. There was tenderness on the right side of the rectum.

The blood pressure was 124 systolic, 85 diastolic. The temperature was 98.6°F., the pulse 80, and the respirations 20.

The examination of the blood revealed a hemoglobin of 95 per cent and a white-cell count of 10,000. The urine was negative. A blood Hinton test was negative.

An operation was performed on the fifth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. FRED SIMMONS: Many of the data presented in the record may have no time relation to the incident that led the patient to undergo surgery, since there was an undefined interval between the time she was seen in the Out Patient Department and in the ward. The history tells us that eleven years before entry she had a child and that at the time of entry she was only twenty-seven. So she must have been married at fifteen, and her husband died at about the time the infant was born. She went four years without the possibility of pregnancy and then remarried. Seven years elapsed during which she presumably tried for a child but did not secure one. These data lead one to suspect an inflammatory process in the genital tract. However, I should like to point out that

*Nicholls, M. R., Longcope, W. T., and Williams, R. Occurrence and significance of myocardial failure in acute hemorrhagic nephritis. *Bull John Hopkins Hosp.* 64:83-113, 1937.

it is becoming increasingly important to consider the male partner in any question of sterility. There is no mention of the husband here.

The urinary tract reveals the possibility of disease. She had nocturia two or three times. The recorded urine probably was not a catheterized specimen and therefore the findings are not entirely reliable. But it is of some significance that there were occasional red cells, 7 white cells and 15 epithelial cells per high-power field. This case reminds me of a girl who had abdominal pain, with little in the line of urinary symptoms. Palpation revealed a slightly tender mass in the left vault the size of an English walnut or perhaps larger; x-ray studies revealed a sac full of stones. She was cystoscoped and a slight slit made in the left ureter produced twenty-seven stones. She had a ureteroceles at the base of the ureter where it joined the bladder. That could be the case here.

The pelvic examination in the Out Patient Department was undoubtedly made by a different examiner from the one on the ward. Therefore the 4-cm. tender mass felt by the former and the orange-sized mass felt by the latter could be the same. One examination was made when the patient was in pain, and the other when she was not. One examination was perhaps made by a house-officer, and the other by a visiting man. I cannot be sure but I should like to think for the purpose of what I am going to say later on that there was a change in size in the mass. The leukorrhea in relation to these episodes of pain and the fact that she had a profuse vaginal discharge are rather pertinent even if the cervical smear and culture were negative. As you all know, in the acute stage of a Neisserian infection of the adnexa, culture or smear may fail to show organisms.

The situation before admission to the ward certainly sounds like pelvic inflammatory disease, probably bilateral, with almost certainly a right salpingitis.

We learn from the history that the menarche started at fourteen and that the periods were always regular, with a twenty-eight-day cycle, and lasted three days, with no pain. The last catamenia began five days before the patient entered the hospital.

Since she had been having abdominal pain for at least a week before entry, it must have continued throughout the menstrual period. The fact that the patient had had this period allows me to rule out all complications of pregnancy—

ectopic gestation, early abortion and all that sort of thing.

Tenderness on the right side of the rectum suggests diseases of the gastrointestinal tract. I believe one should mention in the differential diagnosis appendicitis, appendiceal abscess, mucocele and Meckel's diverticulum. Another possibility is dermoid cyst, of which we see ten or twelve cases a year in this hospital. Many are unilateral. The bilateral ones are frequently picked up only by pelvic examination, or demonstrated by x-ray, especially if they have teeth in them. Another possibility that should be considered but that can be ruled out by the menstrual history is a ruptured corpus hemorrhagicum. If this attack had occurred midway in the cycle, between the twelfth and twentieth days, such a diagnosis would have to be thought of. The patient could have a persistent corpus luteum—a frequent cause of sterility.

It is obviously impossible to make an exact diagnosis on the data presented. I shall make a diagnosis of pelvic inflammatory disease, with possibly a twist of a hydrosalpinx.

CLINICAL DIAGNOSIS

Pelvic inflammatory disease.

DR. SIMMONS'S DIAGNOSES

Pelvic inflammatory disease, bilateral.
Right hydrosalpinx, with torsion?

ANATOMICAL DIAGNOSIS

Dermoid cyst of ovary.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: When this patient was explored a large yellow cystic mass was found in the right ovary. Both tubes were entirely normal and so was the appendix. The ovarian mass was removed and proved to be a dermoid cyst full of cheesy material and hair; it contained no teeth, bone or any structures that would have been shown by x-ray examination. Nothing was discovered to account for the acute attack of pain that brought her into the hospital on the last occasion. There was no twisted pedicle or any other lesion to explain why this cyst, which evidently had been present for some years, should have suddenly produced symptoms.

DR. SIMMONS: Was the mass the reason for operation?

DR. MALLORY: Yes; the preoperative diagnosis was the same as yours—pelvic inflammatory disease.

NEW AGENTS IN THE TREATMENT OF INFECTIOUS DISEASES

THE search for new weapons is a part of modern warfare, and there is no denying the fact that the development of new weapons to aid in the defeat of bacterial infections is well under way. Every physician is familiar with the phenomenal results that have been achieved from the use of the sulfonamides, and now other agents are being discovered, that may be useful in the treatment of infections that fail to respond to the sulfonamides. Among those under investigation at present are the so-called "antibiotic" agents—that is, substances that destroy or so modify biotin that it cannot be used by bacteria for their normal growth.

It has been known for many years that certain bacteria, such as *Pseudomonas pyocyaneus*, elaborate substances that are inhibitory as well as lethal to bacteria. Fleming,¹ in 1929, described a soluble substance, "penicillin," which he obtained from the growth of *Penicillium notatum*, that inhibited the growth of gram-positive organisms in vitro. It was nontoxic to animals when given in relatively large quantities, and it was used by him for the local treatment of ocular infections.

A few years later Dubos and Avery² described an enzyme that was obtained from the growth of a bacillus obtained from soil and that was capable of removing and destroying the capsular material of the Type 3 pneumococcus. Other enzymes were derived from bacteria that would act the same way with several other types of pneumococci. Later, Dubos³ isolated a substance from another species of soil bacillus, *Bacillus brevis*; it was called "tyrothricin." This material is bactericidal for gram-positive organisms and can be separated into two fractions—"gramicidin" and "tyrocidine." Other antibiotic agents have been described recently and include "glyotoxin," "actinomycin," "citrinin" and "aspergillin." Of all these agents, tyrothricin and penicillin have been studied most intensively. In a recent number of *War Medicine*, Rammelkamp⁴ summarizes the results that he obtained with tyrothricin in the treatment of infections. Reports on the use of penicillin are beginning to appear from England (Florey and his associates⁵) and from the United States (Dawson and his colleagues^{6,7}).

It is now clear that tyrothricin can be used locally for the treatment of ulcers of the skin, of wounds of the mastoid process and of empyema due to infection with staphylococci, streptococci and pneumococci. Since the material is relatively insoluble except in alcoholic solution and since it does not penetrate the tissues following local application, its use must be confined to the topical treatment of infections. It cannot be given intravenously because of its toxic reactions; there is, however, no evidence that the material is absorbed from local areas of infection since no signs of intoxication follow its topical use. Further studies

MEDICAL EPONYM

STRÜMPEL-MARIE DISEASE

Adolph Strümpel (1853-1925) in the second volume of the first edition of his *Lehrbuch* (Leipzig, 1884, page 152) described this peculiar form of chronic arthritis. A portion of the translation follows:

Those forms may here be mentioned in passing as a remarkable and, as it seems to us, a distinct disease in which there results a gradual and painless complete ankylosis of the vertebral column and hip joints so that the head, the trunk and the thighs are firmly united to each other and become completely stiff, while all the other joints retain their normal mobility. It is apparent that a characteristic modification of the posture and gait must occur as a result. We have seen two quite similar cases of this peculiar disease.

He discusses the entity in more detail in an article, "Bemerkung über die chronische ankylosierende Entzündung der Wirbelsäule und der Hüftgelenke. [A Note on Chronic Ankylosing Inflammation of the Vertebral Column and Hip Joints]." It was published in the *Deutsche Zeitschrift für Nervenheilkunde* (11: 338-342, 1897) as a comment on the preceding article on the same subject by Bechterew.

Pierre Marie (b. 1853) wrote "Sur la spondylose rhizomélitique [Rhizomelic Spondylosis]" in the *Revue de médecine* (18: 285-315, 1898). A portion of the translation follows:

In the session of February 11 of this year, I presented to the Société médicale des Hopitaux two patients afflicted with a disease whose symptoms, identical in both cases, seemed to me to be sufficiently interesting to be brought to the attention of clinicians. In this preliminary discussion, I indicated the principal characters of this disease entity and particularly stressed the extremely marked rigidity of the spine and the more or less complete ankylosis of the coxofemoral and scapulohumeral joints. Calling attention to the fact that the articulations of the roots of the extremities were affected with this kind of spinal rigidity, I proposed to designate it by the name *rhizomelic spondylosis*. . . .

After a careful review of the facts observed in his cases, he concludes:

It seems to me that it is permissible for clinicians to contrast deforming polyarthritis affecting the small joints of the extremities (acromelic deforming polyarthritis) with the ankylosing process that attacks primarily the spine and the joints at the roots or attachments of the extremities (rhizomelic spondylosis).

MISCELLANY

ARMY-NAVY "E" AWARD TO SHARP AND DOHME, INCORPORATED

Sharp and Dohme, pioneers in the development of dried blood plasma, and producers in their laboratories in Philadelphia and nearby Glenolden not only of plasma but of many other disease-preventing, pain-relieving and life-saving medical supplies for the armed forces, were awarded the Army-Navy "E" for excellence in production on Wednesday, February 10. Since both pharmaceutical and biological laboratories received the award, two ceremonies were held. At each, the "E" pennant was presented by Brigadier General Hugh J. Morgan, chief consultant in medicine, Office of the Surgeon General, United States Army. The pennants were received on behalf of the company by Mr. J. S. Zinsser, the president.

NOTE

Dr. E. B. Astwood and Dr. E. W. Dempsey of the Harvard Medical School have been appointed managing editor and associate managing editor, respectively, of *Endocrinology*. They will have the collaboration of a newly established editorial board consisting of Drs. J. S. L. Browne, E. T. Engle, C. G. Hartman, E. C. Kendall, F. C. Koch, C. N. H. Long and H. B. van Dyke.

BOOK REVIEW

The Ophthalmic Formulary. Compiled by G. Griffin Lewis, M.D. 12°, cloth, 167 pp. Springfield, Illinois: Charles C Thomas, 1942. \$3.50.

In this volume the author has gathered 115 pages of ophthalmic prescriptions catalogued with reference to the eye diseases treated, and has added 27 pages of ophthalmic *materia medica*, 8 pages of index and 12 blank pages for notes.

Historically, just as the interest of the reader centers around the formulas set down in the *Ebers Papyrus* for treatment of the Egyptian ophthalmias, so also does the interest of the reader follow the empirical therapy practiced concurrently by each of the prescription authors of the present volume.

Practically, whether the reader of this volume be a general practitioner or an ophthalmologist, he already recognizes that therapy of today is departing from the field of the empirical and seeking a surer footing in the field of the etiologic and the chemical. Topical and empirical therapy in ophthalmology is nowadays deferring to more effective treatment: retinal detachment is referred at once to the experienced ophthalmic surgeon, and diabetic retinitis to the competent internist, and the exogenous and endogenous ophthalmic infections are discussed with and frequently treated by the chemotherapist.

The prospective buyer will purchase this volume to satisfy his curiosity about the therapeutic approach of his contemporary and departed colleagues, but he will not use it for his *vade mecum* in practice.

SPORADIC INFECTIONS CAUSED BY *SALMONELLA SUIPESTIFER* AND *SALMONELLA ORANIENBURG**

B. V. JAGER, MD,¹ AND MARION E. LAMBERT

BOSTON

SPORADIC cases of *Salmonella suipestifer* infection continue to arouse interest because of their variable clinical manifestations. In the period of one year, 6 patients with this infection were observed at the Boston City Hospital. Two additional patients whom we originally believed to be infected with the organism were subsequently found to be infected with *S. oranienburg*, a closely related bacterium. This report presents the clinical, laboratory and bacteriologic findings of the 8 cases mentioned and a brief discussion in which the bacteriologic identification is emphasized.

CASE REPORTS

CASE 1. A C., a 63-year-old man, was readmitted on November 30, 1940, after having been discharged 5 months previously with a diagnosis of acute posterior coronary thrombosis, chronic bronchitis and arteriosclerotic heart disease with mild cardiac decompensation. Subsequently he was essentially well until 9 days before the present admission, when there was an onset of shaking chills followed by drenching sweats that recurred every evening. In addition there were marked irritability, intermittent mental confusion, anorexia, urinary frequency and progressive weakness.

Physical examination showed a chronically ill appearing male who was moderately confused. The chest was emphysematous. Moist rales were present at the base of each lung posteriorly. The heart appeared to be normal. The blood pressure was 110/60. The liver edge was felt 3 cm below the costal margin. The spleen was not palpable. The left leg was shortened, and the left femur was thickened along its entire shaft. The temperature was 102°F, the pulse 90, and the respirations 28. The hemoglobin was 90 per cent (Sihli). The red cell count was 4,480,000 and the white cell count 13,900 with 78 per cent polymorphonuclear leukocytes, 16 per cent lymphocytes and 6 per cent monocytes. The urine contained a heavy trace of albumin and many leukocytes. The blood Hinton reaction was negative. The plasma non-protein nitrogen was 48 mg per 100 cc.

The patient's course was one of gradual decline with periods of temporary improvement. Anorexia, nausea, weakness, delirium, chills and fever were the salient features. At no time was there any diarrhea or evidence of cardiac failure. During the first 10 days of hospitalization the temperature was persistently elevated, varying between 99° and 102°F. Thereafter there was a remittent type of fever with febrile episodes lasting for 2 to 5 days with intervening periods of subnormal temperature of 5 to 9 days duration. Occasionally rapid temperature rises were accompanied by shaking chills. The pulse varied between 70 and 110 and the respirations between 20 and 25. The hemoglobin fell gradually to 60 per cent. The white-cell count varied between 7500 and 15,000. Subsequent plasma non-protein nitrogen determinations showed no significant change from the initial level of 48 mg per 100 cc until the last week, when there was a rise to 199 mg. The urine, which had a maximum specific gravity of 1.030, consistently contained large amounts of albumin and variable numbers of leukocytes. The results of two lumbar punctures were negative. Two electrocardiograms showed no significant abnormality.

Röntgenograms of the chest were interpreted as emphysema, except for a film 2 days before death that showed a patchy infiltration at the base of the right lung. A film of the left femur showed changes consistent with osteitis fibrosa cystica within the shaft.

The patient received digitalis and toward the latter part of the illness parenteral fluids and small transfusions. From December 25 to January 2, 1941, he received a total of 46 gm of sulfadiazine without appreciable response, and from January 19 to 22 10 more. He became progressively weaker and died on January 29 approximately 10 weeks after the onset of the present illness. Terminally the clinical picture was that of uremia.

A blood culture taken on the day of admission was positive for *S. suipestifer*. Cultures taken on December 1, January 11, 15, 19, 24 and 29 were also positive for this organism, whereas those taken on January 6 and 16 were sterile. Neither of the sterile cultures was taken at a time when the patient was receiving chemotherapy. Between December 1 and January 29 seven urine cultures were positive for *S. suipestifer* and one taken on January 6 was sterile. Two stool cultures, a culture of sputum and a culture of prostatic secretion failed to yield this organism. On four occasions between December 8 and January 20 the patient's serum agglutinated his own organism and stock strains of *S. suipestifer* to a dilution of 1:640.

Bacteriologic, Boston City Hospital.

Autopsy (performed 2 hours after death). The heart was moderately enlarged and weighed 610 gm. There was a slight dilatation of the apex of the heart, with softening of the muscle in this region and thickening of the overlying pericardium. On section the myocardium of the apex of the left ventricle was markedly thinned and on the underlying endocardial surface there was a large, firmly adherent, yellow thrombus which almost filled the lower half of the left ventricular chamber. The coronary arteries showed moderate sclerotic changes. The heart valves were normal. The right lower lobe of the lung showed a patchy pneumonic consolidation with multiple miliary abscesses. Elsewhere the lungs appeared normal. The spleen was slightly enlarged and at one pole there was a small yellow infarct. The liver was normal. The gastrointestinal tract was normal, except for a small duodenocolic fistula. The kidneys showed no significant abnormality other than a small infarct in the right kidney. The mucosal surface of the bladder was gray-black and roughened about the trigone. The left femur showed a fusiform dilatation of the shaft with destruction and replacement of bone by firm, gray tissue.

Histologically, the myocardium of the apex of the heart showed almost complete replacement by dense scar tissue. The attached mural thrombus showed evidence of organization in the deeper portion and superficially it was composed of fibrin, platelets and leukocytes. These changes indicated that the myocardial lesion was of at least several months' duration. The splenic infarct appeared recent in origin. The liver parenchyma was normal. The kidneys showed minimal changes that were consistent with slight benign nephrosclerosis. Sections of the left femur were consistent with localized osteitis fibrosa cystica.

A post-mortem culture of the heart's blood was sterile. A swab inserted in the endocardial thrombus was positive for *S. suispestifer*. Type 29 pneumococcus was the only organism cultured from the right lower lobe of the lung. Cultures of the spleen, of the liver, of bile aspirated from the hepatic duct and of the feces were negative for *S. suispestifer*. Gram-Weigert and MacCallum-Goodpasture stains of sections of myocardium, of the endocardial thrombus and of the splenic infarct showed no bacteria, so that it was impossible to prove satisfactorily that the endocardial thrombus was the focus responsible for the prolonged septicemia, in spite of the fact that the endocardial thrombus yielded *S. suispestifer*, while the heart's blood was sterile.

The pathological diagnoses were as follows: myocardial infarction, old, with mural thrombus; bronchopneumonia, with miliary abscesses, right lower lobe; slight benign nephrosclerosis; acute cystitis; small duodenocolic fistula; localized osteitis fibrosa cystica, left femur; surgical absence of gall bladder; and infarcts of spleen and right kidney.

CASE 2. C. M., a 48-year-old man, was admitted on March 19, 1941, because of dysuria and frequency of 2 months' duration.

The temperature was 98.6°F., the pulse 110, and the respirations 20. The heart and lungs were normal. The blood pressure was 160/100. Both kidneys were palpable, and there was moderate costovertebral tenderness on the right. The urine contained a heavy trace of albumin and many leukocytes. The hemoglobin was 90 per cent (Sahli), the red-cell count was 4,160,000, and the white-cell count was 12,200. The blood Hinton reaction was negative. The plasma nonprotein nitrogen level was 38 mg. per 100 cc. A retrograde pyelogram showed a single large stone in the dilated pelvis of the right kidney.

The day after admission the right kidney was removed. For the first 12 postoperative days, the patient was acutely ill, with the temperature varying between 100 and 103°F. thereafter the temperature was normal. On the 5th postoperative day, cough and pulmonary rales appeared. A roentgenogram was interpreted as indicating bronchopneumonia. At this time the patient was given 6 gm. of sulfathiazole daily for 1 week. He developed an anemia, with the hemoglobin falling to 60 per cent (Sahli), and the red-cell count to 3,000,000. Throughout the illness the white-cell count remained moderately elevated, varying between 10,000 and 20,000. Differential counts taken from the 2nd to 5th week of hospitalization showed from 60 to 80 per cent polymorphonuclear leukocytes and from 8 to 20 per cent monocytes, the rest of the cells being lymphocytes. The albumin disappeared from the urine within several days after operation; however, leukocytes were persistently present. At the time of operation, and on three subsequent occasions during the first 2 postoperative weeks, *S. suispestifer* was cultured from the wound. No preoperative urine cultures were obtained. Three blood cultures during the febrile postoperative period were sterile. Cultures of the throat, stools, urine and bile were negative for *S. suispestifer*. On the 7th postoperative day the patient's serum agglutinated his own organism and stock strains of *S. suispestifer* to a dilution of 1:640. He was discharged well on April 26.

The resected right kidney measured 18 by 9 by 5 cm. The renal cortex was narrowed, and there was a tremendous dilatation of the calyces and renal pelvis. A single stone, 3 cm. in diameter, was in the renal pelvis. Histologically the kidney showed changes consistent with hydronephrosis, pyelitis and slight chronic pyelonephritis. There were no abscesses in the renal parenchyma.

CASE 3. I. M., a 21-year-old, unmarried woman, was admitted on February 23, 1941, because of severe, crampy, right lower abdominal pain of 4 days' duration. This was accompanied by headache, feverishness, obstipation, nausea, anorexia and drowsiness. There were no chills, vomiting or diarrhea. There was no history of intercourse.

On examination the patient appeared moderately ill. The temperature was 101°F., and the pulse 120. The heart and lungs were normal. The liver and spleen could not be palpated. There was rebound tenderness in the right lower quadrant of the abdomen. The following day an exploratory laparotomy was performed. The appendix and the left fallopian tube were normal, whereas the right fallopian tube appeared markedly enlarged, thickened and reddened. There was a small amount of fibrinous exudate in the pelvis. A right salpingectomy and an appendectomy were performed. A culture of the pelvic exudate yielded *S. suispestifer*. Postoperatively the patient received 6 gm. of sulfanilamide daily for 3 days. The temperature and pulse fell slowly to normal by the 5th postoperative day. Convalescence was uneventful.

At the time of admission, the hemoglobin was 70 per cent (Sahli), the red-cell count 4,040,000, and the white-cell count 11,600. Subsequent white-cell counts varied between 7000 and 9000 with 60 to 70 per cent polymorphonuclear leukocytes and 4 to 8 monocytes, the rest of the cells being lymphocytes. The stools and urine were normal.

S. suispestifer was recovered from the pelvic exudate at operation on February 24. The same organism was recovered from cultures of the abdominal wound on three occasions during the next 3 weeks. Cultures of the throat, urine, stools, bile and cervix did not yield this

organism On March 2, the patient's serum failed to agglutinate her own organism or stock strains of *S. suis* agglutifer On five subsequent occasions between March 12 and 27, her serum agglutinated her own organism and stock strains of *S. suis* agglutifer to a dilution of 1:640

The resected fallopian tube was distended with thin sanguinopurulent material Histologically the changes were those of chronic salpingitis and pyosalpinx with a superimposed acute inflammatory reaction

CASE 4 E. P., a 4-year-old girl, was readmitted on January 8, 1941 Three weeks previously she had been discharged from this hospital, having made an uneventful convalescence from pertussis Except for a slight cough she was well until 1 week before the present admission, when there was an onset of fever and cough productive of blood tinged sputum

At the time of admission the patient appeared acutely ill The tonsils were moderately enlarged and injected The heart appeared to be normal Fine rales were heard throughout the entire chest, although there was no evidence of consolidation The remainder of the examination was negative The temperature was 105°F, the pulse 148 and the respirations 48 Laboratory studies showed the urine to be normal The hemoglobin was 92 per cent (Sahli), the red cell count 5,650,000, and the white cell count 8600, with 42 per cent polymorphonuclear leukocytes, 48 per cent lymphocytes and 10 per cent monocytes An x-ray film of the chest was interpreted as showing bronchopneumonia in the right hilar area The patient was given sulfathiazole, 0.5 gm every 4 hours for 48 hours On the 3rd hospital day, the temperature, pulse and respirations returned to normal Convalescence was uneventful On the 8th day, the hemoglobin was 67 per cent (Sahli) and the white cell count 12,400, with 62 per cent polymorphonuclear leukocytes and 38 per cent lymphocytes

A blood culture on January 9, the day after admission, was positive for *S. suis* agglutifer On January 14 and 20 the patient's serum failed to agglutinate her own organism and stock strains of *S. suis* agglutifer From a throat culture taken on January 15 at a time when the patient was afebrile, a Type 18 *A. pneumoniae* was recovered A urine culture on January 15 was sterile The patient was discharged on January 26 with a diagnosis of *S. suis* agglutifer bacteremia and bronchopneumonia

CASE 5 R. M., a 35-year-old man with a long history of alcoholism, was admitted on August 19, 1940 For 6 months he had had a chronic productive cough accompanied by anorexia, night sweats and loss of weight The day of admission he developed diarrhea and frequent shaking chills

On physical examination the patient appeared both acutely and chronically ill The temperature was 103°F, the pulse 90 and the respirations 20 The only abnormal finding in the chest was bronchial breathing at the right lung base posteriorly The liver was enlarged, extending 9 cm below the right costal margin The spleen was not palpable The patient had a severe macrocytic anemia There was no achlorhydria The white-cell count was 3400, with 62 per cent polymorphonuclear leukocytes, 32 per cent lymphocytes and 6 per cent monocytes Subsequent counts varied between 6000 and 12,000 The urines and stools were normal Roentgenograms of the chest showed changes consistent with bronchiectasis of the right lower lobe

The patient remained in the hospital for 8 weeks The diarrhea subsided within 24 hours The temperature rose to 102°F on the 2nd day, returned to normal on the 3rd day, and for the next 10 days showed frequent rises to 99 or 100°F Thereafter the patient was afebrile The pulse varied between 80 and 110 The patient slowly gained weight and strength The macrocytic anemia responded to liver therapy The liver decreased in size Liver function tests on several occasions showed no impairment

A blood culture taken on the day of admission was positive for *S. suis* agglutifer Subsequent cultures of the blood, urine, stools, sputum and bile were negative for this organism The patient's serum on August 27 and September 11 failed to agglutinate his own organism and stock strains of *S. suis* agglutifer He was discharged on September 13 with a diagnosis of *S. suis* agglutifer septicemia chronic alcoholism, early cirrhosis of the liver, macrocytic anemia of undetermined etiology, malnutrition and bronchiectasis

CASE 6 W. C., a 44-year-old man, was admitted on October 23, 1940 There was a history of chronic alcoholism For the past 4 months there had been an intermittent productive cough Two weeks before admission, the patient had several shaking chills which were followed by sweats Two days later, he experienced a pleuritic type of pain in the region of the right lower chest and his cough became productive of brownish sputum The present illness was attended by malaise and dull epigastric pain

Physical examination revealed a well developed, poorly nourished man who appeared moderately ill The tongue, which showed moderate atrophy of the papillae, exhibited a coarse tremor There was slightly diminished resonance over the left chest anteriorly and posteriorly and occasional rales were heard in these areas The heart appeared to be normal The blood pressure was 154/90 The liver edge was felt at the right costal margin The spleen was not palpable Physical examination was otherwise negative

The temperature was 100.8°F, the pulse 112, and the respirations 28 The hemoglobin was 89 per cent (Sahli) The red cell count was 3,850,000 The white-cell count was 4600, with 54 per cent polymorphonuclear leukocytes, 44 per cent lymphocytes and 2 per cent monocytes Subsequent counts varied between 4800 and 5200 Repeated examinations of the urine and stools were normal The blood Hinton reaction was negative On repeated examinations of the sputum, no tubercle bacilli were present A roentgenogram showed the lung fields to be clear

The patient received supportive treatment supplemented by vitamin therapy The temperature remained elevated for the 1st week of hospitalization, varying between 99 and 101°F, and thereafter was normal The pulse varied between 70 and 90 On the 4th hospital day, the patient became jaundiced, with an icteric index of 25 Four days later the jaundice had subsided At the onset of the jaundice the liver edge was palpable 4 cm below the costal margin Recovery was gradual

A blood culture on October 29, 6 days after admission, yielded *S. suis* agglutifer Subsequent blood cultures taken on October 31 and November 1 and 2 were sterile On October 28, a Type 14 *A. pneumoniae* was recovered from the sputum A culture of urine on November 2 and stool cultures on November 2 and 4 were negative for *S. suis* agglutifer The patient's serum on November 2, 8 and 19 agglutinated his own organism and stock strains of *S. suis* agglutifer to a dilution of 1:640

The patient was discharged on November 24 with a diagnosis of chronic alcoholism, acute infectious hepatitis, early cirrhosis of the liver, deficiency of vitamin B complex and *S. suispestifer* bacteremia.

Certain findings in this small series of 6 cases of *S. suispestifer* infection deserve comment. Only 1 case occurred in a child, the remaining 5 in adults. In no case was the source of infection determined.

Harvey¹ divided 71 cases of sporadic *S. suispestifer* infection into clinical groups. Most numerous were the typhoidlike infections, in which there were no localizing signs. Fever, anorexia, vomiting, headache and diarrhea were the commonest symptoms. The pulse was usually rapid. Mild bronchitis was frequent in older patients. A second large group of patients had pulmonary involvement, as evidenced by bronchopneumonia, occasional lobar pneumonia, pleurisy with effusion and empyema. A third group included suppurative bone and joint lesions due to this organism. A fourth group was comprised of infections complicating surgical procedures. In additional groups were placed the more unusual complications, such as involvement of the nervous system, endocarditis and urinary-tract infection.

Two of our 6 cases of *S. suispestifer* infection fall into the group with typhoidlike symptoms. In Case 1, however, the anatomical findings suggested that an endocardial thrombus might have been a focus of infection, although this could not be established with certainty. In this respect, the case was more analogous to a *S. suispestifer* endocarditis, which has occasionally been observed.²⁻⁵

In 5 cases there was clinical or roentgenologic evidence of pulmonary involvement. In 2 cases (Cases 4 and 6) the pulmonary complications were a prominent feature in the present illness, while in 2 others (Cases 1 and 2) they appeared to be incidental. In Case 5, the pre-existing bronchiectasis seemed unrelated to the present illness. In all 6 cases, cultures of the sputum or throat failed to yield *S. suispestifer*. In Cases 4 and 6, pneumococci recovered from the sputum and from a throat culture may have been responsible for the pulmonary infection. In Case 1, at autopsy there was a bronchopneumonia. Cultures from the affected lobe yielded only Type 29 pneumococcus. In only 6 of the 24 cases of *S. suispestifer* infection with pulmonary complications described by Harvey¹ was there bacteriologic proof that this organism was responsible for the pulmonary changes. Kuttner and Zepp⁶ describe the case of a two-year-old child who had *S. suispestifer* bacteremia. At autopsy this organism was recovered from the heart's blood, whereas a Type 3 pneumococcus and the influenza bacillus were the only organisms

present in cultures of the lungs. These observations suggest that pulmonary involvement occurring during the course of this infection may be caused by other bacteria that may be regarded as accompanying or secondary infections.

Cases of *S. suispestifer* infection in which the urinary-tract infection has a prominent role in the clinical symptoms are unusual.¹ In Case 2, a large single renal calculus causing obstruction was associated with *S. suispestifer* infection in the involved kidney.

Acute abdominal conditions resulting from *S. suispestifer* infection have been relatively frequent. Kuttner and Zepp⁷ described a case of fibrinous peritonitis due to this organism. Walker, Weiss and Nye⁸ described a case of *S. suispestifer* bacteremia complicated by a large splenic abscess. From a case with chronic cholecystitis, they cultured from the gall bladder an organism which although not fully identified was presumed to be *S. suispestifer*. In Case 3 of our series, there was a unilateral salpingitis with a localized fibrinous peritonitis from which *S. suispestifer* was cultured. Herring and Nicholson⁹ described a case with bilateral acute salpingitis and pelvic peritonitis due to this organism. TenBroeck and his co-workers¹⁰ described a *S. suispestifer* infection in association with an induced abortion and subsequent sepsis. Boller¹¹ observed a *S. suispestifer* infection associated with postpartum sepsis. In a case described by Gray,¹² *S. suispestifer* septicemia was associated with multiple infected uterine myomas.

Certain other clinical findings were of interest in our series. Fever was present in 5 cases at the time of admission and developed in the other post-operatively. Two patients had chills. Diarrhea occurred only once. Relative bradycardia occurred once. There was enlargement of the liver in 3 cases; in 2, however, there was a history of chronic alcoholism. Jaundice occurred in 1 case and was of brief duration. Splenomegaly was not observed. Chemotherapy, which was employed in 4 cases, did not seem to have a beneficial effect in any. Four patients were debilitated prior to the onset of the illness, either by previous illness or chronic alcoholism.

The blood findings deserve mention. A moderate anemia was present or developed during the course of the illness in 4 cases; in several of them, however, chemotherapy may have been a factor in its production. In 3 cases the initial white-cell count was low or normal, whereas in 3 it was elevated. In 2 cases the urine contained albumin and leukocytes.

In 4 of the 5 cases in which blood cultures were made, the organism was recovered. Urine cultures were positive in only 1 case. Stool cultures were

negative in every case. Prostatic secretion in 1 case and culture of the cervix in 1 did not yield this organism. Sputum or throat cultures were made in every case, but *S. supestifer* was not recovered. Cultures of the bile were made in 3 cases and gave negative results. Cultures of the wounds in the 2 cases with surgical complications

flagellar antigen *c* *S. paratyphi* C (*Bacterium paratyphosum* C, eastern European type of *S. supestifer*, Hirschfeld type) is likewise diphasic and may occur in the group phase with flagellar components 1, 4 and 5 or in the type specific phase with the flagellar antigen *c*. In addition, there are several allied types of *S. supestifer* that differ

TABLE 1 Fermentation Reactions

gave repeatedly positive results. In 4 cases, the patients' serums agglutinated their organisms. In 3, this was manifest during the third or fourth week of illness and may have appeared earlier. In 1 case, the duration of the illness could not be ascertained. In 2 cases, the patients' serums did not agglutinate their organisms by the fourth week and no subsequent studies were made.

S. supestifer is a gram negative motile bacillus that can be separated from other members of the *Salmonella* group by its selective fermentation reactions and by agglutinations with specific anti-serums. It belongs in Group C of the Kauffmann-White classification¹³ of the typhoid paratyphoid organisms. The organisms in Group C have in common at least one of the two somatic antigens V and VII. The term "*Salmonella supestifer*" includes several organisms that have both the somatic antigens VI and VII but differ slightly in their flagellar antigenic components and in their selective fermentation reactions (Table 1). *S. cholerae suis*, var. *kunzendorf* (monophasic, western European type of *S. supestifer*, Group II of Andrews¹⁴) is a monophasic organism with group flagellar antigens 1, 3, 4 and 5, which are shared by certain other members of the *Salmonella* group. *S. cholerae suis* (diphasic, American strain of *S. supestifer*, Group I of Andrews) exists in two phases. In one phase, this organism has the group flagellar antigens 1, 3, 4 and 5, which are identical with those of the monophasic organism (*S. cholerae suis*, var. *kunzendorf*), whereas in the other phase this organism has only the type specific

slightly in their selective fermentation reaction but have the same antigenic structure.

According to Kauffmann,¹³ the majority of diphasic *Salmonella* organisms tend to occur predominantly in the specific phase when freshly isolated. Such an organism gives rise to substrains that occur in the specific phase and the group phase.^{13, 14} It is apparent that organisms of the diphasic strain can occur predominantly in the non-specific phase in a given culture. In this event, *S. cholerae suis*, a diphasic organism, would be antigenically indistinct from *S. cholerae suis*, var. *kunzendorf*, a monophasic type. It was formerly assumed that monophasic types never give rise to substrains of the diphasic type. This view has been refuted by Bruner and Edwards,^{15, 16} who were able to obtain diphasic strains from monophasic strains by special culture technique. Under ordinary cultural conditions, however, this change did not occur.

The six strains of *S. supestifer* isolated from our cases belong to the type *S. cholerae suis*, var. *kunzendorf*, a monophasic organism. In America, infections in man from both the diphasic type (*S. cholerae suis*) and the monophasic type (*S. cholerae suis*, var. *kunzendorf*) have been observed. In recent years, however, the monophasic type has been found more frequently.^{4, 6, 10} To our knowledge, the Hirschfeld strain (*S. paratyphi* C) has not been found in this country.

From selective fermentation reactions, our six strains belonged to the monophasic type. For absolute identification, agglutinin absorption studies

The patient was discharged on November 24 with a diagnosis of chronic alcoholism, acute infectious hepatitis, early cirrhosis of the liver, deficiency of vitamin B complex and *S. suispestifer* bacteremia.

Certain findings in this small series of 6 cases of *S. suispestifer* infection deserve comment. Only 1 case occurred in a child, the remaining 5 in adults. In no case was the source of infection determined.

Harvey¹ divided 71 cases of sporadic *S. suispestifer* infection into clinical groups. Most numerous were the typhoidlike infections, in which there were no localizing signs. Fever, anorexia, vomiting, headache and diarrhea were the commonest symptoms. The pulse was usually rapid. Mild bronchitis was frequent in older patients. A third group included suppurative bone and joint lesions due to this organism. A fourth group was comprised of infections complicating surgical procedures. In additional groups were placed the more unusual complications, such as involvement of the nervous system, endocarditis and urinary-tract infection.

Two of our 6 cases of *S. suispestifer* infection fall into the group with typhoidlike symptoms. In Case 1, however, the anatomical findings suggested that an endocardial thrombus might have been a focus of infection, although this could not be established with certainty. In this respect, the case was more analogous to a *S. suispestifer* endocarditis, which has occasionally been observed.²⁻⁵

In 5 cases there was clinical or roentgenologic evidence of pulmonary involvement. In 2 cases (Cases 4 and 6) the pulmonary complications were a prominent feature in the present illness, while in 2 others (Cases 1 and 2) they appeared to be incidental. In Case 5, the pre-existing bronchiectasis seemed unrelated to the present illness. In all 6 cases, cultures of the sputum or throat failed to yield *S. suispestifer*. In Cases 4 and 6, pneumococci recovered from the sputum and from a throat culture may have been responsible for the pulmonary infection. In Case 1, at autopsy there was a bronchopneumonia. Cultures from the affected lobe yielded only Type 29 pneumococcus. In only 6 of the 24 cases of *S. suispestifer* infection with pulmonary complications described by Harvey¹ was there bacteriologic proof that this organism was responsible for the pulmonary changes. Kuttner and Zepp⁶ describe the case of a two-year-old child who had *S. suispestifer* bacteremia. At autopsy this organism was recovered from the heart's blood, whereas a Type 3 pneumococcus and the influenza bacillus were the only organisms

present in cultures of the lungs. These observations suggest that pulmonary involvement occurring during the course of this infection may be caused by other bacteria that may be regarded as accompanying or secondary infections.

Cases of *S. suispestifer* infection in which the urinary-tract infection has a prominent role in the clinical symptoms are unusual.¹ In Case 2, a large single renal calculus causing obstruction was associated with *S. suispestifer* infection in the involved kidney.

Acute abdominal conditions resulting from *S. suispestifer* infection have been relatively frequent. Kuttner and Zepp⁷ described a case of fibrinous peritonitis due to this organism. Walker, Weiss and Nye⁸ described a case of *S. suispestifer* bacteremia complicated by a large splenic abscess. From a case with chronic cholecystitis, they cultured from the gall bladder an organism which although not fully identified was presumed to be *S. suispestifer*. In Case 3 of our series, there was a unilateral salpingitis with a localized fibrinous peritonitis from which *S. suispestifer* was cultured. Herring and Nicholson⁹ described a case with bilateral acute salpingitis and pelvic peritonitis due to this organism. TenBroeck and his co-workers¹⁰ described a *S. suispestifer* infection in association with an induced abortion and subsequent sepsis. Boller¹¹ observed a *S. suispestifer* infection associated with postpartum sepsis. In a case described by Gray,¹² *S. suispestifer* septicemia was associated with multiple infected uterine myomas.

Certain other clinical findings were of interest in our series. Fever was present in 5 cases at the time of admission and developed in the other post-operatively. Two patients had chills. Diarrhea occurred only once. Relative bradycardia occurred once. There was enlargement of the liver in 3 cases; in 2, however, there was a history of chronic alcoholism. Jaundice occurred in 1 case and was of brief duration. Splenomegaly was not observed. Chemotherapy, which was employed in 4 cases, did not seem to have a beneficial effect in any. Four patients were debilitated prior to the onset of the illness, either by previous illness or chronic alcoholism.

The blood findings deserve mention. A moderate anemia was present or developed during the course of the illness in 4 cases; in several of them, however, chemotherapy may have been a factor in its production. In 3 cases the initial white-cell count was low or normal, whereas in 3 it was elevated. In 2 cases the urine contained albumin and leukocytes.

In 4 of the 5 cases in which blood cultures were made, the organism was recovered. Urine cultures were positive in only 1 case. Stool cultures were

16,400, with 90 per cent polymorphonuclear leukocytes and 10 per cent lymphocytes. Subsequent counts varied between 7800 and 10,000. The urine contained a heavy trace of albumin and many leukocytes in the sediment. A Type 33 pneumococcus was cultured from the sputum. A roentgenogram showed consolidation of the right middle lobe of the lung.

The patient was given 0.5 gm of sulfathiazole every 4 hours for 3 days. The temperature fell to normal on the 2nd day and then rose again, reaching 104°F on the 4th day. On the 5th day it returned to normal, where it remained. The physical signs of pneumonia and diarrhea disappeared by the 7th day. The diarrhea recurred on the 10th day and continued for 5 days. The urine consistently showed heavy traces of albumin, although there were no leukocytes in the urinary sediment after the 4th day. The plasma nonprotein nitrogen determination on the 7th day was 46 mg per 100 cc.

A blood culture taken the day after admission yielded *S. oranienburg*. A culture on April 14 was sterile. Urine cultures on April 15 and 19 and May 5 did not yield this organism. *S. oranienburg* was recovered from stool specimens on April 10 and 15, but not from stool cultures on May 7 and 8. A throat culture on April 15 was negative for this organism. On April 15 and May 27 the patient's serum agglutinated his organism to a dilution of 1:160.

S. oranienburg is a rare pathogen. Kauffmann¹⁸ isolated it from several healthy individuals and from the stools of 3 children with diarrhea. Rimpau and Steinert¹⁹ isolated it repeatedly from the stools of a healthy carrier, whose serum did not agglutinate the organism. They also isolated this organism from the stool of a woman with acute gastroenteritis. This patient's serum was found to agglutinate her organism to a dilution of 1:200 when tested eight days after onset of illness.

S. oranienburg is a monophasic organism which has the somatic antigens VI and VII and the type specific flagellar antigens *m* and *t*. As noted in Table 1, the selective fermentation reactions of this organism are identical with those of *S. paratyphi C*. If, however, we had carried out fermentation tests with Stern's glycerol medium and Bitter's rhamnose medium,¹⁸ it would have been possible to make a differentiation, since *S. oranienburg* gives positive fermentation reactions on these two mediums, whereas *S. paratyphi C* yields negative reactions. With stock *S. supestifer* serum, *S. oranienburg* gives a somatic (finely granular) type

of agglutination. This is in accord with their common somatic antigens. The diphasic *S. supestifer* (*S. cholerae suus*) serum absorbed with the monophasic strain (*S. cholerae suus*, var. *kunzendorf*) failed to agglutinate the two *S. oranienburg* strains. This is to be expected, since the two organisms have distinct flagellar antigens. When injected subcutaneously and intraperitoneally into mice, the two *S. oranienburg* strains proved lethal.

SUMMARY

Six sporadic human cases of infection with *S. supestifer* are described. Clinically these cases showed great variation. The bacteriologic identification of this organism and its separation into types are discussed. Two cases of *S. oranienburg* infection are described, and the close bacteriologic similarity of this organism with *S. supestifer* is considered.

RHEUMATOID ARTHRITIS AS A CAUSE OF INCREASED CEREBROSPINAL-FLUID PROTEIN*

A Study of One Hundred and One Patients

ALFRED O. LUDWIG, M.D.,† CHARLES L. SHORT, M.D.,† AND WALTER BAUER, M.D.‡

BOSTON

THE neurologic manifestations of rheumatoid arthritis are numerous, extremely variable and at times so striking as to simulate disease of the central or peripheral nervous system. They comprise evidence of increased vasomotor activity, such as cold, clammy, cyanotic extremities, vasospasm, tachycardia and visual-field defects; sensory phenomena, including paresthesia, changes in sensory perception and referred radiating pains with radicular or segmental distribution; abnormalities of the motor system marked by muscular weakness, atrophy and hyperirritability, leading to tremor, twitchings, cramps and changes in the tendon reflexes; and possibly trophic changes of the skin, hair and nails. One or more such clinical features of the disease have been observed in 66 per cent of 293 unselected consecutive patients with rheumatoid arthritis. An analysis of these findings and the results of detailed neuropathological studies will be the subject of a future report.¹

The present investigation, concerning the cerebrospinal-fluid findings in rheumatoid arthritis, was begun in 1935. In the meantime, Graber-Duvernay and Gerbay,² employing an inexact method for the determination of protein, reported an elevated cerebrospinal-fluid protein in 8 of 15 patients with moderate to severe rheumatoid arthritis, of whom only 1 had spondylitis. A little later, Marron,³ using a tyrosine equivalent method for protein analysis, noted cerebrospinal-fluid proteins varying from 31 to 60 mg. per 100 cc. in 6 cases of arthritis of the spine, unspecified as to type. Except for these two papers, a search of the literature has failed to reveal any reference to the subject.

MATERIALS AND METHODS

The cerebrospinal fluids examined during the course of this study were obtained from 101 patients with rheumatoid arthritis, of whom 59 suffered from peripheral-joint disease alone and 42

from spondylitis, with or without peripheral-joint involvement. All were under our personal observation, many being in the group of 293 cases previously referred to. The diagnosis of spondylitis was based on stiffness, pain, tenderness, limitation of motion and deformity of the spine. There was frequently a history of sciatica or intercostal, segmental or pleuritic pain. Straight leg-raising was usually limited and often associated with some restriction of the motions of either the hips or shoulders or both. As a rule the chest expansion and vital capacity were markedly reduced. Increased knee and ankle jerks were commonly found, and an absent Achilles-tendon reflex (at the time the sciatica was present), meralgia paraesthetica and other neurologic abnormalities were demonstrable in some cases. Roentgenologic evidence of disease of the sacroiliac or spinal articulations was present in all but 1 of the spondylitis group, the exception being an early case with typical findings of rheumatoid spondylitis. All these patients had elevated sedimentation rates.

Since it was soon apparent that cerebrospinal fluid abnormalities were encountered more frequently in the patients with spondylitis, we included more patients with this type of rheumatoid

TABLE 1. Distribution of Patients according to Age and Sex.

arthritis. As a result, the age and sex distribution of the cases studied and the ratio of one group to the other are not the same as they would be in an unselected consecutive series (Table 1). However, it will be seen from Table 2 that the distribution by duration and severity of disease is more nearly comparable to what one might expect to find in an unselected group of cases.

Cerebrospinal-fluid analyses* were repeated in 11 cases (7 with and 4 without spondylitis), with intervals ranging from two weeks to three years. The following chemical methods were used: sugar, Folin⁴; chloride, Wilson and Ball⁵;

TABLE 2. *Distribution of Patients according to Duration and Severity of Disease.*

protein, Ayer, Dailey and Fremont-Smith⁶; colloidal-gold curve, Lange.⁷ We have considered the following values as being characteristic of normal cerebrospinal fluid⁸: initial pressure, 70 to 180 mm. of water (pressures of 180 to 200 mm. and greater than 200 mm. are thought to be questionably abnormal and definitely increased respectively); leukocytes, 0 to 5 cells per cu. mm.; sugar, 50 to 100 mg. per 100 cc.; chlorides, 695 to 762 mg. per 100 cc.; protein, lumbar fluid, 15 to 45 mg. per 100 cc., and cistern fluid, 15 to 25 mg. per 100 cc.; colloidal-gold curve, no change greater than 2 in each tube.

RESULTS

The initial pressure, measured in 93 cases, was normal in all but 7. In 5 it was questionably abnormal (in 1 case 195 mm. and in 4 cases 200 mm. of water), and in 2 it was definitely high (210 and 250 mm. of water). In only 1 of the latter was the protein content increased. In the absence of

in the other 3 cases (46.0, 48.0 and 48.5 mg. per 100 cc.) are not significant. The chloride determinations in only 3 of 34 cases were lower than normal (693, 690 and 670 mg. per 100 cc.). Minor reductions of this type, particularly when not accompanied by other changes, are of no diagnostic importance.⁸ Similarly, we did not regard as significant total protein values of 12 to 14 mg. per 100 cc.⁸ observed in fluids from 5 patients in the group with peripheral-joint involvement alone, 4 of whom were under eighteen years of age.

The number of patients having increased cerebrospinal-fluid proteins and abnormal colloidal-gold curves is shown in Table 3. It will be noted that the percentage of fluids showing an increased protein content was significantly higher in the spondylitis group than in the group with

TABLE 4. *Increased Cerebrospinal Fluid Protein Contents and the Colloidal Gold Reactions in Patients without Spondylitis.*

other abnormalities, these slightly increased initial pressures probably represent incomplete relaxation of the patient. Pleocytosis was present in 3 cases, but all the fluids were contaminated with blood in sufficient quantity to explain the increase in white cells. In 41 of 44 cases the sugar determinations were normal. The slight reductions observed

spondylitis are listed separately in Table 4. Fluids from 3 other patients in this group exhibited an increased colloidal-gold reaction but were otherwise normal; these curves are shown in Table 5.

Thus it will be seen that only 9 of the 59 patients with rheumatoid arthritis involving the peripheral joints alone had spinal-fluid alterations, 4 having increased proteins, 2 (J. Mcl. and B. D.) with associated abnormal gold-sol curves, and 3 having only abnormalities of the gold-sol curve

*The cerebrospinal fluid determinations were carried out in the Spinal Fluid Laboratory of the Massachusetts General Hospital by Miss Eulizia Grebeniowska and Mrs Charles McCann, to whom we are indebted for their services.

The latter changes usually occurred in the first and middle zones. Lumbar punctures were repeated in 4 cases from this group. In 2, both fluids were normal. In patient J. McL., re-examination confirmed the finding of a previous high protein,

but in patient W. S. D. the second fluid was normal. He entered the hospital complaining of acute rheumatoid arthritis and frequent nocturnal erections. Although the protein was elevated at that time, there was no evidence of neurologic disease. A urethral stricture was present and was thought.

to explain the genital symptoms. Re-examination was made three years later, at a time when the arthritis was quiescent but the erections continued.

Increased cerebrospinal-fluid protein was found in 12 of the 42 patients having spondylitis. The values are given in Table 6. Two of these 12 patients (H. E. and J. dP.) and 4 others without associated high protein had abnormal gold-sol curves. The latter are shown in Table 7.

Of the 7 patients in the spondylitis group in whom the spinal fluid was examined on more than

one occasion, 3 were consistently abnormal (high protein, with or without abnormal gold-sol curves), 2 were consistently normal except for a questionably abnormal initial pressure in 1, and 2 (R. G. and H. E.) showed a high protein content or an abnormal gold-sol curve on some occasions and were normal on others. (See Table 6.)

Thus it will be seen that 23 of the 101 patients had cerebrospinal-fluid alterations, 16 with increased protein contents, with or without accompanying increased colloidal-gold reactivity, and 7

TABLE 7. *Abnormal Colloidal-Gold Reactions in Cerebrospinal Fluids without Increased Protein Content in Patients with Spondylitis.*

with abnormal colloidal-gold curves only. As previously noted, 12 of the 16 patients with elevated proteins had spondylitis. In view of this finding, it is of considerable interest that 3 of the 4 patients (all males) in the group with peripheral-joint involvement showing elevated proteins had clinical symptoms suggestive of spondylitis at the time of the lumbar puncture. A definite diagnosis of spondylitis was not justified at the time, but one of the patients (J. R. W.) developed roentgenologic changes in the sacroiliac articulations at a later date. The fact that 15 of the 16 patients with increased proteins had either spondylitis (12 cases) or symptoms indicative of spinal involvement (3 cases) strongly suggests a relation between an elevation of the cerebrospinal-fluid protein and the presence of rheumatoid arthritis in the spinal and sacroiliac articulations. In the 2 patients with high proteins in whom cistern punctures were also performed (J. McL. of the peripheral group and M. L. V. of the spondylitic group), the fluid also showed an elevation of protein (40 and 31 mg. per 100 cc., respectively), as did fluid taken simultaneously from the dorsal region in the case of J. McL.

No significant relation could be established between the level of the spinal-fluid protein and the age or sex of the patients with spinal involvement (except that spondylitis occurs predominantly in males), the duration or total severity of the disease or the sedimentation rate. Table 8 shows that severe pain or sciatica or both were much more frequent in the high-protein group, which suggests that these patients were suffering from more active disease.

DISCUSSION

It is generally agreed that abnormal gold sol curves are related to the cerebrospinal fluid albumin globulin ratio, the globulin fraction be

TABLE 8 Incidence of Severe Pain and Sciatica in Spondylitis Patients with and without Increased Cerebrospinal Fluid Protein Contents

SYMPTOMS	PROTEIN CONTENT		PERCENTAGE DIFFERENCE	
	NO	%	NO	%

ing more active in causing the reaction⁸⁻¹¹ More recently, Kabat et al.,¹¹ employing the Tiselius electrophoresis apparatus, showed that in certain

in the globulin (the latter resulting in abnormal gold sol curves) are due chiefly to an increased permeability of the spinal-cord membranes as a result of their proximity to acutely inflamed articular tissues. The findings in Tables 8 and 9 are consistent with such a premise. That the increased permeability is greatest in the lumbar region is suggested by the diminishing protein content of fluids taken simultaneously from higher levels (the dorsal region and the cisterna magna). In these cases, the protein increase was not uniformly distributed through the subarachnoid space, as is the case in a metabolic disorder, such as myxedema.⁸

Diagnostic Implications

The diagnosis of spondylitis, especially in early cases, may at times be extremely difficult. This is particularly true of patients having an increased cerebrospinal fluid protein, complaining of back pain with sciatic radiation (increased by coughing

diseases all the colloidal gold reactivity was found in the gamma globulin fraction and none in the albumin fraction. They stated, "Although the colloidal gold reacting material is found in the gamma fraction, it may differ from the normal gamma component of spinal fluid, since other fluids which contain equally large amounts of gamma globulin yield normal colloidal gold curves." They were also able to demonstrate that cerebrospinal fluid proteins show a similar pattern to that of the serum proteins. Since it is known that the serum albumin globulin ratio may be reversed in patients with rheumatoid arthritis, with or without elevation of the serum protein,¹²⁻¹⁴ it seemed logical to suspect that the spinal fluid protein and colloidal gold curve abnormalities were a reflection of alterations in the serum proteins. The latter were determined in too small a number of cases to draw any definite conclusions. The data suggest, however, as shown in Table 9, that, in cases with spondylitis, abnormal gold sol curves are related to elevation of the serum globulin. It is possible that these abnormalities are related, in part, to the types or concentrations of globulin in such cases.¹¹ However, it is more likely that changes in the total cerebrospinal fluid protein or

and sneezing) and exhibiting flattening of the lumbar curve, diminution of motion of the lumbar spine and of straight leg raising, and atrophy and weakness of the muscles of the thighs and legs. The neurologic examination is, as a rule, negative except for hyperreflexia, although meralgia paraesthetica and an absent Achilles tendon reflex are rarely observed. In such cases the diagnostic possibilities include ruptured intervertebral disk, intraspinal neoplasm, metastatic malignant disease, a thickened ligamentum flavum, arachnoiditis, subarachnoid hemorrhage following trauma, and rarely diabetic neuritis, syringomyelia and multiple sclerosis. It is not within the scope of this paper to discuss in detail the diagnosis of each of these conditions.

The presence of a ruptured intervertebral disk has been suspected in a number of the spondylitic patients in this series. Two of them (Q M and W N B) had negative lipiodol reactions, and in 1 (Q M) a negative exploration of the spinal canal was carried out at another hospital because of a suspected ruptured intervertebral disk. The clinical differentiation should as a rule be relatively easy. In the case of a ruptured intervertebral disk, the onset is usually acute, and a history of injury is

present in about 80 per cent of cases,^{15, 16} absent or diminished ankle jerks in 50 to 70 per cent,^{15, 16} anesthesia or hypoaesthesia of the leg or foot in 35 per cent^{15, 16} and a positive lipiodol reaction in over 90 per cent.^{15, 16} On the other hand, in patients with spondylitis the onset is insidious, a history of injury is infrequent, neurologic abnormalities are uncommon, and the lipiodol reaction is negative.

The diagnosis of rheumatoid arthritis of the spine is frequently missed because the examiner is not cognizant of its symptoms and signs. In fact, a careful history alone should often serve to differentiate rheumatoid spondylitis from a ruptured intervertebral disk. In addition to the symptomatology and signs of spondylitis previously mentioned, these patients frequently complain of pain in areas of the spine other than the lumbar and sacral regions. Their symptoms are always worse on awakening and associated with generalized stiffness. They rarely obtain relief on lying down. Most of them admit suffering from general malaise, easy fatigability, anorexia and weight loss, often preceding the onset of the articular symptoms. Finally, the characteristic roentgenographic changes in the sacroiliac joints (narrowing, irregularity, haziness, decalcification and increased bone formation, occurring alone or simultaneously and eventually leading to fusion) usually occur early in the disease. Occasionally, the history, physical findings, and cerebrospinal fluid and roentgenologic examinations are not sufficiently characteristic to allow one to make the diagnosis. In such cases only the passage of time will allow for progression of the disease and the establishment of the correct diagnosis.

SUMMARY

The cerebrospinal fluids from 101 patients with rheumatoid arthritis, 42 having spondylitis with or without peripheral arthritis, and 59 having involvement of the peripheral joints alone, were examined.

The only significant abnormalities observed were increased protein contents, abnormal colloidal-gold curves or a combination of the two.

Nine, or 12 per cent, of the 59 patients with rheumatoid arthritis involving the peripheral joints alone and 16, or 38 per cent, of the 42 patients with spondylitis exhibited such abnormalities.

Fifteen of the 16 patients with increased cerebrospinal-fluid protein had either spondylitis or symptoms suggesting spinal involvement. This fact points strongly to a relation between an elevation of the spinal-fluid protein and the presence of rheumatoid arthritis in the spinal and sacroiliac articulations.

Cerebrospinal-fluid alterations occurred more frequently in the spondylitis patients with severe pain or sciatica or both and hence presumably with a higher degree of inflammatory activity.

Factors probably involved in the production of these abnormalities are alterations in the serum proteins and increased permeability of the meninges from their proximity to inflamed articular tissue.

Attention is called to the diagnostic difficulties presented by patients with rheumatoid spondylitis and increased cerebrospinal-fluid protein, with particular reference to their differentiation from cases with ruptured intervertebral disks.

MEDICAL PROGRESS

THE MECHANISM OF HEART FAILURE AND RELATED STATES (concluded)*

LAURENCE B. ELLIS, M.D.†

BOSTON

Circulatory Changes Subsequent to Treatment

It has already been brought out that as a result of the treatment of congestive failure with digitalis and other measures, the cardiac output usually improves, although not to the level that existed prior to failure. Harrison,³⁵ however, has emphasized that this improvement in volume flow is not invariable nor does it bear any close relation to the change in clinical symptomatology; and Starr⁹ has published examples of improvement in heart failure accompanied by a decrease in output. Starr has also presented data obtained with the ballistocardiogram indicating that the initial dose of digitalis may produce a temporary increase in cardiac output greater than that which persists when the full digitalizing effect is obtained.

The well-known value of the application of multiple tourniquets in the treatment of acute pulmonary edema is given objective experimental confirmation in the studies of Ebert and Stead,³⁶ who show that the application of such tourniquets can result in a temporary diminution in the circulating blood volume averaging 720 cc., and that this measure is thus temporarily the equivalent of a good-sized venesection.

Certain changes observed with the onset of diuresis have been discussed in the previous section. Proger, Ginsburg and Magendantz,³⁷ Schroeder,³⁸ Schemm³⁹ and Ellis⁴⁰ have shown the value of restriction of sodium in the diet in controlling cardiac edema.

The rationale for weight reduction in heart disease receives confirmation in the work of Master et al.,⁴¹ who have demonstrated that the oxygen consumption, cardiac output and cardiac work are diminished when overweight subjects undergo weight reduction. Proger and Magendantz⁴² had previously shown a reduction in cardiac output and cardiac work of patients with congestive heart failure subjected to prolonged dietary restriction.

Subnormal Circulation and Neurocirculatory Asthenia

A clinical picture that has posed a problem to physicians is that of patients who complain of weakness, giddiness when upright, fainting and a host of related symptoms. Some such patients are chronically troubled by these complaints and are usually labeled as having neurocirculatory asthenia; in others the symptoms develop only during or after an acute infection or some other debilitating disease. It has long been recognized that in such patients the circulation is inadequate. Starr and Jonas⁴³ have recently shown by ballistocardiographic studies that many of these patients, together with many elderly people with arteriosclerosis, and patients with coronary disease and with heart block, have inadequate cardiac outputs. The diminution of cardiac output in many of these patients, especially those with neurocirculatory asthenia and the postinfectious group, is not necessarily on a cardiac basis, but may well be due to inadequate peripheral compensation and poor return of blood to the heart. Starr has, however, also demonstrated that some patients, likewise diagnosed as having neurocirculatory asthenia, whose symptoms are somewhat similar have normal or increased cardiac outputs, and he suggested a separation of the two types. The symptoms of the latter group in many ways resemble Graves's disease. They complain of nervousness, tachycardia, palpitation, dizziness and dyspnea on exertion. The underlying etiology of the disturbed circulation in patients with neurocirculatory asthenia is of course not clarified by these investigations. The disturbance is probably due to central autonomic nervous stimuli arising in patients who are constitutionally predisposed to react in this fashion when under strain.

Shock and Cardiac Failure

What in many ways is an extreme and acute aggravation of the type of symptoms previously described as exhibited by patients with a subnormal circulation is the clinical picture usually called shock or peripheral circulatory collapse—extreme weakness, stupor, sweating, cyanosis, cold extremities, drop in blood pressure and so forth. It is

*Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress Annual*, Vol. III, 1942 (Springfield, Illinois: Charles C. Thomas Co.).

†Laboratory and the Second and Fourth City Hospital, and the Department

Associate in Medicine, Harvard Medical School; assistant physician, Thorndike Memorial Laboratory, and assistant visiting physician, Boston City Hospital.

generally believed that this is essentially a phenomenon of disturbance of the peripheral circulation, with a disproportion between the capacity of the peripheral vascular bed and the circulating blood volume. Some recent work has indicated that in certain circumstances an element of heart failure may be involved. Ebert and Stead⁴⁴ have presented evidence that in the shock picture occurring terminally in overwhelming infections there is little or no diminution in plasma volume and the venous pressure is relatively well maintained, and they believe that injury of both the heart and the peripheral circulation is involved. The same authors⁴⁵ have also carried out studies suggesting that a similar shock syndrome occurring in patients with acute myocardial infarction or chronic congestive failure may be due to cardiac failure alone.

Wiggers and Werle⁴⁶ found that the heart as well as the peripheral circulation may be involved in experimental shock. They state:

The capacity of the ventricles to respond to a given venous pressure is reduced, perhaps due to a prolonged reduction in coronary blood flow. The results strongly suggest that this is one of the factors which precipitate an irreversible circulatory state. Although the observations are limited to shock from a prolonged period of posthemorrhagic hypotension with reinfusion of blood, they nevertheless suggest that we may have accepted too hastily the theory that the myocardium is unimpaired in shock and that the course of circulatory failure cannot be benefited by the use of cardiac stimulants.

Circulatory Dynamics in Specific Types of Cardiovascular Disease

Fast and slow ventricular rates. Stewart and his co-workers⁴⁷ have shown that abnormal cardiac rhythms associated with fast ventricular rates, such as auricular fibrillation or flutter and supraventricular or ventricular tachycardia, are inefficient, leading to a decreased cardiac output per minute and per beat, dilatation of the heart and decrease in the amount of work done by it. On the other hand, slow ventricular rhythms, such as those that occur in high-grade heart block, are relatively efficient. Although the cardiac output per minute is somewhat reduced, the output per beat is greatly increased, the heart does not dilate, and the work accomplished is commensurate with the size of the heart.

Valvular heart disease. Stewart et al.⁴⁸ have made cardiodynamic studies that bear out the clinical impression long held regarding the degree of strain imposed on the heart by valvular lesions. Single lesions are not incompatible with normal function of the heart, but a combination of defects, such as mitral stenosis and insufficiency, is always,

according to their observations, accompanied by reduction in function. Patients with mitral disease and aortic regurgitation show less functional impairment than do those with mitral involvement alone; in other words, aortic regurgitation is of functional benefit. Aortic stenosis in combination with other lesions always results in marked decrease in function.

Bazett, LaPlace and Scott⁴⁹ presented observations on 2 subjects with free aortic regurgitation in whom the amount of blood regurgitated was 16.6 and 31 per cent, respectively, of the total ejected by the left ventricle. The total output of the left ventricle in this condition is thus greatly elevated and its work may be increased by 50 per cent or more.

Adhesive pericarditis and pericardial effusion. Stewart et al.⁵⁰ found that constrictive pericarditis results in a decrease in cardiac output and an elevation of venous pressure owing to interference with the inflow of blood to the right side of the heart and possible impairment of contraction. In another paper⁵¹ they reported essentially similar results in pericardial effusions. In both conditions with removal of the tamponade the cardiodynamics returned to normal.

Congenital cardiovascular defects. An important study by Eppinger, Burwell and Gross⁵² on 6 patients with uncomplicated patent ductus arteriosus brings out the astonishing fact that the amount of blood flowing through the patent ductus may be from 4 to 19 liters per minute, representing from 45 to 75 per cent of all the blood pumped by the left ventricle. The increased work load on the heart and especially on the left ventricle is obvious.

Stewart and Bailey⁵³ carried out measurements in 14 cases of coarctation of the aorta and found that the output of the heart was normal or even increased before the onset of failure. Because of the elevation of blood pressure in the aorta, the work of the left ventricle in these patients was increased. Nevertheless only 5 of the patients showed cardiac enlargement, and when this occurred the prognosis was poor. The nature of the hypertension in this condition has long been the subject of study and speculation. It has been held that it is neurogenic in nature,⁵⁴ but this has been denied (Pickering⁵⁵). Recently, as the result of Goldblatt's demonstration that chronic hypertension may be produced experimentally by reduction in renal blood flow, the thesis has been advanced that coarctation of the aorta is in essence a "Goldblatt clamp" that reduces renal blood flow, and that this in turn releases a hormonal vasoconstrictor mechanism. Evidence in favor of this belief is contributed by Friedman et al.,⁵⁶ who have

found a substantial reduction in renal blood flow in 6 patients with coarctation and by the experimental work of Ryland,⁵⁷ who obtained essentially similar results. If the hypertension of coarctation is similar to Goldblatt's experimental hypertension, one would expect a generalized vasoconstriction with increase in peripheral resistance, and not one limited to regions proximal to the aortic constriction. That this is indeed the case is suggested by the work of Steele,⁵⁸ who by direct measurements of intra-arterial pressure found that in the femoral arteries of such patients the diastolic pressures were elevated to an extent comparable to that in the arms, although the pulse pressures were unusually low.

Pulmonocardiac Failure

Although much attention has been paid in the Continental literature to "kyphoscoliotic heart disease," there has been comparatively little in English and American publications on this subject. Chapman, Dill and Graybiel,⁵⁹ however, have recently reported in detail the clinical and physiological features of this condition. Dyspnea, palpitation and fainting in patients with marked chest deformities are warning signs—signs unfortunately often mistakenly attributed to a neurosis. Although these patients may develop congestive failure of the usual type, this is unusual; sudden profound circulatory or respiratory collapse, frequently unresponsive to treatment, is common. The clinical state is different from that of the usual chronic cor pulmonale, or right-sided heart failure occurring in patients with chronic pulmonary disease such as emphysema, pulmonary fibrosis and so forth. The disturbed circulatory function in pulmonocardiac failure is dependent chiefly on interference with pulmonary dynamics—reduction in vital capacity, increase in residual air and inefficient pulmonary exchange of gases, with deficient arterial oxygenation, together with the great mechanical difficulty in respiratory movements.

Kerwin⁶⁰ reported 5 patients with pulmonocardiac failure in whom dyspnea and cyanosis were the most prominent clinical features. He pointed out what had been previously observed by Chapman, Dill and Graybiel and others, that hypertrophy and dilatation of the right side of the heart regularly occur, suggesting that chronic pulmonary hypertension had existed during life.

SUMMARY

Recent investigations concerning alterations in circulatory physiology that occur in various types

of heart disease and in heart failure are discussed especially as they bear on the explanation of clinical signs and symptoms. The numerous and complex factors concerned with the production and maintenance of clinical manifestations such as dyspnea or edema are brought out.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29101

PRESENTATION OF CASE

A fifty-two-year-old man entered the hospital because of abdominal pain.

Approximately four years prior to admission the patient first suffered from attacks of crampy abdominal pain that were relieved by belching and cleared spontaneously after several weeks. He remained quite well until one year before entry, when he noted mild exertional dyspnea, which became worse six months later and was associated with easy fatigability. At that time he "strained his back" and was confined to bed for one month, when the back discomfort completely cleared. Six weeks before admission he began to suffer from attacks of lower abdominal crampy pain that extended across the abdomen, but apparently had no further radiation. Occasionally, the pain made the patient double up. The attacks usually lasted five to fifteen minutes and occurred irregularly during the day. There was no relation to meals but at times the pain occurred after fatty meals. There was no associated nausea, jaundice, fever or chills. Soda occasionally provided some relief and at times the pain was relieved by voiding. The bowels moved regularly, but the patient had taken a cathartic every day during the three weeks prior to admission. The stools were never bloody, tarry or acholic but at times were rather loose. Three weeks before entry his abdomen began to swell and he had some distress in the right upper quadrant, which had no apparent relation to the lower abdominal pain. This continued to the time of admission. Two weeks prior to admission, orthopnea developed and the patient required three pillows for rest in bed. No leg edema had been noticed. He then developed a cough that was productive of small amounts of yellowish sputum; there was no chest pain, but he did complain of a sense of fullness and aching at the costal margins. During the illness he had lost approximately 20 pounds. During the five years prior to admission, the patient's diet was irregular and of poor quantity and quality. He often missed two meals during a single day. He denied any more than "one drink a week."

The patient's mother died at seventy-four of "cancer," and his father died at seventy-six of "stoppage of the bowel." The past history was noncontributory.

Physical examination revealed a well-built man who had lost a great deal of weight. He belched frequently but appeared to be comfortable. The heart and lungs were normal. The abdomen was distended and tympanitic. No masses were felt, and no tenderness was elicited. A fluid wave was demonstrable. The inguinal lymph nodes on both sides were enlarged, firm, discrete, nontender and freely movable.

The blood pressure was 120 systolic, 80 diastolic. The temperature was 98.8°F., the pulse 90, and the respirations 20.

Examination of the blood revealed a hemoglobin of 13.2 gm. per 100 cc. and a white-cell count of 12,100. The urine was normal. The blood Hinton test was negative. The nonprotein nitrogen was 22 mg. per 100 cc., the chloride 97.7 milliequiv. per liter, and the protein 4.7 gm. per 100 cc. A flat plate of the abdomen demonstrated considerable air in a dilated stomach, but there was no evidence of dilated small or large bowel. There were numerous fine flecks of calcification that had the appearance of gall stones. The density of the abdomen was suggestive of fluid, but this may have been due in part to the patient's size. No air was seen within the biliary tree. A Graham test showed no filling of the gall bladder. There was dye in the stomach. A barium enema passed to the midsigmoid, where it met a complete obstruction. Insufficient barium passed the point of obstruction to demonstrate the type of lesion. There was considerable gas in slightly dilated loops of small bowel and in the descending colon.

An operation was performed on the third hospital day.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD L. YOUNG: The exertional dyspnea and easy fatigability could indicate an old man getting older, or they could suggest the beginning of cardiac failure.

"There was no relation to meals but at times the pain occurred after fatty meals." This is a suggestion of gall-bladder trouble, as are the pains spoken of earlier that were relieved by belching. Gaseous distention of the stomach may cause pressure on a damaged gall bladder, and hence pain, which may be relieved by belching.

Although not at all diagnostic, the fact that soda relieved the pain is again of interest. If you ask a patient how and he says, "It makes me belch gas," that also makes you think of gall bladder. The

relief of ulcer pain by soda is a chemical rather than a mechanical relief.

In spite of the fact that we are taught in school to consider one diagnosis for the cause of symptoms, one has only to look at the diagnoses going out from this department to realize that all the patients we are dealing with have more than one anatomic lesion. This patient may have had gall stones and some other condition more recently.

The commonest cause of weight loss is cancer. The patient also had a suggestive family history.

On physical examination the patient belched frequently. Ninety-nine out of a 100 patients who sit down before you and belch will prove, if you watch them carefully, to be cribbers.

"The abdomen was distended and tympanitic." The one who reported that ought to have been more explicit. If it was tympanitic everywhere there was no fluid wave. Of course if he had said there was tympany in the midline, dullness in the flanks, and a fluid wave we might believe it; but the man was of good size, with a big belly, and had lost weight, and I defy anyone to be sure of a fluid wave under such conditions.

The enlarged lymph nodes are possibly important, probably not. The protein was below the so-called "edema level."

"No air was seen within the biliary tree." That is an interesting observation. It makes one think that the examiner was wondering about gallstone ileus. The only way I know of explaining air in the biliary tree is by a direct opening from the gall bladder into the intestine, which is also the only way a large gallstone gets into the intestine. Under these conditions we do occasionally see air in the biliary tree. Would you say that was so, Dr. Holmes?

DR. GEORGE W. HOLMES: Yes.

DR. YOUNG: We are not told about occult blood in the stool. Is that important? We are entitled to ask if there was enough coming from the bowel to test for occult blood. Of course we are given the strong suggestion that this man had gallstones. I am going to ask Dr. Holmes if he would be willing to be more explicit.

I do not believe we have any right to consider gallstone ileus on the basis of this story because the obstruction was in the midsigmoid. I have never known a gallstone to make trouble at that point. A gallstone can make trouble at various places in the small bowel, where it acts as an obturator. It often goes to the ileocecal valve and there makes trouble. Although the patient may have had gallstones, I do not believe they are the cause of his trouble.

In a man of this age coming in with a story of crampy pains and this appearance in the x-ray

films, one first has to settle whether there is an obstruction that requires operation. Let us immediately say, "Yes." Then Dr. Mallory will ask what it was due to. The patient was fifty-two years old and may well have had malignant disease. That is always the first thing to consider. Malignant disease can fit this picture throughout—the crampy pains going on for a brief period beforehand, the slight loss of blood and the anemia.

What other things should one think of? We have thrown out gallstone ileus. I shall be arbitrary and say that it is not that. Could it be tuberculosis? The patient had questionable fluid in the belly. That either came from metastatic malignancy of the peritoneum or from tuberculosis. I doubt if it was tuberculosis for such lesions are commoner on the right side, in the region of the ileocecal valve. They do occur with some frequency on the left side, often enough so that we ought to consider tuberculosis. Diverticulitis could account for these symptoms but not for fluid in the peritoneal cavity. It could account for the white-cell count, which is slightly elevated, and a localized diverticulitis may have been the cause of the trouble, even though no diverticula were seen in the x-ray films. I cannot throw out the diagnosis completely.

What else is there? Intussusception gives a characteristic rectal discharge of mucus and prune-juice material; I believe that its absence rules out the diagnosis. Then there is the question of a large polypoid leiomyosarcoma, which is rare.

In other words this comes down to a question of obstruction due to malignant disease, diverticulitis or a combination of the two. Please remember that they can occur together. The important thing is what to do. There is one other thing we see about once a year in the hospital, namely, old people with merely a fecal impaction. We do a cecostomy, and when the smoke has cleared away we have nothing else to account for the difficulty. The thing to do here is to relieve the obstruction. Going merely on the theory of chances, I shall say that the cause was carcinoma of the sigmoid, with diverticulitis the second choice. It will not hurt my feelings to have it prove to be the second, but it will hurt my feelings to have it prove to be anything but one of these two. I should like Dr. Holmes to add anything he can from the x-ray films.

DR. HOLMES: There is positive evidence of gallstones, but there is nothing to make me think of gallstone ileus. In the first films there is little evidence of gas in the abdomen, and the more or less ground-glass appearance of the abdomen suggests the presence of a considerable amount of fluid. At no time was there an excessive amount

of gas in the small bowel. At one time the stomach was considered dilated with gas and there was more or less gas in the large bowel.

One thing of interest is that at no time was there much gas in the rectum.

DR. YOUNG: Was there loss of mucosa in the obstructed area?

DR. HOLMES: I do not believe so. I agree with the record: all that one can say is that the patient had obstruction. That is surprising. In diverticulitis or carcinoma, one can usually guess what the cause of the trouble is. These films, however, give no evidence other than that of obstruction.

DR. YOUNG: I might mention hernia, volvulus and other things, but I do not believe they deserve serious consideration.

DR. FLETCHER H. COLBY: I should like to ask Dr. Young if diverticula are apt to cause complete obstruction.

DR. YOUNG: No; but neither does cancer. There is generally a trickle to give a clue.

DR. HOLMES: That is true.

DR. REGINALD H. SMITHWICK: What is the level of the obstruction?

DR. HOLMES: It is near the rectosigmoidal junction.

DR. SMITHWICK: Do you think it is beneath the peritoneal inflection?

DR. HOLMES: I cannot answer that.

CLINICAL DIAGNOSES

Carcinoma of sigmoid.
Carcinomatosis peritonei.

DR. YOUNG'S DIAGNOSES

Carcinoma of sigmoid.
Carcinomatosis.

ANATOMICAL DIAGNOSES

Carcinoma of gall bladder, with regional metastases and diffuse peritoneal implantation.
Obstruction of sigmoid by adhesions.
Ascites.
Pulmonary edema.
Cholelithiasis.

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: This patient was explored, and a presumably primary tumor was found in the region of the sigmoid. It was apparently thought that the degree of obstruction was not severe enough to necessitate a colostomy; so a specimen was taken and the surgeon backed out without doing anything more. The patient gradually accu-

mulated more and more ascitic fluid, slowly failed and died.

Autopsy showed that the gallstones were directly connected with the intestinal obstruction but not in the form of gallstone ileus. The gall bladder contained many small stones, as Dr. Holmes pointed out, and one of the dangers of symptomless stones in the gall bladder is that they may induce carcinoma. There was a primary cancer of the gall bladder, a characteristic polypoid growth within the lumen of the organ. It had invaded the liver extensively and had metastasized to the lymph nodes around the head of the pancreas; at first there seemed to be cancer of the pancreas, but on dissection it became clear that the pancreas was surrounded by tumor but uninvolved. There were generalized peritoneal implantations, and these were most marked in the dependent portions of the abdomen. In the pelvis the cancer had grown in a diffuse sheet over the serosa of the sigmoid, anchoring it in the shape of a sharp S. The obstruction was due to the kinking rather than to anything else. The mucosa was uninvolved and it was quite possible to follow around the curves one at a time with an instrument, but functionally it was, as has been said, a fairly complete obstruction.

DR. YOUNG: How much fluid was in the belly?

DR. MALLORY: There were many encapsulated pockets of fluid, each quite separate from the other.

DR. YOUNG: Was this a separate tumor in the sigmoid or was it a metastatic tumor from the gall bladder?

DR. MALLORY: It was a peritoneal metastasis from the tumor in the gall bladder.

A PHYSICIAN: How about the lungs?

DR. MALLORY: They showed massive pulmonary edema, which was, I am sure, a terminal complication. The heart was normal.

DR. HOLMES: Was this man peritoneoscoped?

DR. MALLORY: No.

CASE 29102

PRESENTATION OF CASE

A forty-six-year-old Greek machinist entered the hospital because of swelling of the abdomen.

Six months prior to admission the patient noticed the onset of ankle edema. This became progressively worse, and three weeks before entry his abdomen began to swell. At that time he lost his appetite, felt nauseated and frequently vomited everything that he ate. His family noticed that he had lost his ruddy color and seemed yellow. This color deepened during the second week of his

illness but during the week prior to admission it began to fade. During the three weeks before entry he had had diarrhea four or five times a day, usually after eating, and his stools were described as yellowish but never clay colored. His diet was limited to milk and soups during this period. He developed an irritating nonproductive cough, and dyspnea requiring two pillows at night. The urine became dark, but this was unassociated with urinary symptoms other than nocturia (four or five times), which he had had for a year. Pain was not a prominent feature of the illness, but three weeks before entry he experienced a vague discomfort in the right back. During the next week he had occasional attacks of knifelike pain radiating from both flanks to the umbilicus, and later he had upper abdominal pain that radiated around to the back on both sides. The longest attack lasted two hours.

The patient consumed only a "moderate" amount of alcohol, and more than a jigger or two daily. There was no history of exposure to industrial solvents.

The family and past histories were noncontributory.

Physical examination disclosed a thin man who was not in obvious distress despite a markedly distended abdomen. The skin was dark and sallow. The scleras were yellow tinged. The diaphragm was high, particularly on the right. There were scattered crackling inspiratory rales at both bases of the lungs. Examination of the heart was negative. The abdomen was markedly distended and tense. A fluid wave was easily demonstrated and there was shifting dullness in both flanks. The liver edge was palpable 7 cm. below the costal border, and the edge was smooth. There was pitting edema of both lower extremities to the knees.

The blood pressure was 110 systolic, 70 diastolic. The temperature was 99°F., the pulse 100, and the respirations 22.

Examination of the blood revealed a red-cell count of 6,400,000 with a hemoglobin of 90 per cent, and a white-cell count of 6000, with 81 per cent polymorphonuclear leukocytes. The urine was acid in reaction, had a specific gravity of 1.024 and showed a +++ test for bile; the sediment contained 8 to 10 white cells per high-power field. The blood Hinton test was negative. One stool gave a +++ guaiac test, but two later examinations were negative. The van den Bergh was 3.8 mg. per 100 cc., direct, and 6.2 mg., indirect. The serum nonprotein nitrogen was 22 mg. per 100 cc., the chloride 97.7 milliequiv. per liter, and the protein 8.1 gm., the albumin 2.3 gm. and the globulin 5.8 gm. per 100 cc., making an albumin-globulin ratio of 0.4. The prothrombin time was 32 seconds (nor-

mal, 20 seconds). The cephalin flocculation test was ++ at 24°C. and ++++ at 40°C. A barium meal of the upper gastrointestinal tract showed marked curling of the lower esophagus; this area was slightly irritable and regurgitation occurred. A hiatus hernia measuring 2 by 2 cm. in diameter was seen, but there was no evidence of varices. The stomach was not remarkable. The duodenum and small intestines appeared normal so far as seen; however, examination was handicapped by the large amount of ascites. A barium enema passed from the rectum to the cecum without delay. There was no evidence of intrinsic disease in the rectum and colon. There appeared to be some depression or displacement of the sigmoid inferiorly, and the ascending and descending colon lay well laterally. No soft-tissue mass was demonstrated.

In spite of supportive treatment and paracentesis the patient failed rapidly. He became unable to retain any food or fluids. A flat plate of the abdomen after paracentesis demonstrated a markedly enlarged spleen. The lower aspect was not visible because of overlying intestinal gas. However, it reached almost to the level of the iliac bone. The shadow of the liver was apparently not enlarged. The patient died on the thirteenth day after admission.

DIFFERENTIAL DIAGNOSIS

DR. REED HARWOOD: I am sorry there is no roentgenologist here. "Curling" of the esophagus is supposedly due to adhesions and is of no particular significance except that it may sometimes be confused with esophageal varices. Esophageal varices were not demonstrated in this case. I should like to ask if the spleen was palpated after paracentesis, and if it did reach down as far as the iliac bone. The record indicates that the spleen was enormous, yet I see the iliac crest here and what I take to be the lower border of the spleen lies considerably above it. Would you agree with me, Dr. Jones, that the spleen is large but not enormous?

DR. CHESTER JONES: The stomach shadow appears to be pushed over to the midline. It is hard to be sure, but I should agree that the shadow you indicate is probably spleen. There was so much fluid in the abdomen when that film was taken that many outlines are obscured.

DR. HARWOOD: Another question I should ask the roentgenologist is, Do you think the spleen has pushed the descending colon laterally?

DR. CHESTER JONES: It does not show it in this film.

DR. HARWOOD: I should like to know how the roentgenologist interprets a finding of that sort. It may be significant.

DR. JONES: The two flexures seem to be in about the same position.

DR. HARWOOD: With you as my roentgenologist, Dr. Jones, I am going to take the liberty of discounting the statement that the descending colon was pushed laterally.

In summary we have the case of a patient who had edema, ascites, marked splenomegaly, jaundice, an inverted albumin-globulin ratio and a positive flocculation test. All these point strongly to severe liver damage. My first thought on reading the case over was that the patient had cirrhosis with a rapid progression, perhaps a toxic hepatitis. There are several points that are not entirely consistent with this diagnosis and I shall discuss these at some length.

The spleen, at least according to the interpretation of the X-ray Department, was unusually large for a case of alcoholic cirrhosis. As I read the record, it reminded me of the type of spleen one gets in Banti's disease. However, Banti's disease is a chronic ailment associated with marked anemia, and usually appears in people considerably younger than this man. Then again the jaundice is rather too marked for the ordinary case of alcoholic cirrhosis. However, in a case that is progressing rapidly with marked liver damage, jaundice of this degree could be expected to appear. Then we find that there were no esophageal varices. In alcoholic cirrhosis with a severe degree of ascites and a large spleen one would expect also to find esophageal varices. In addition, the history does not give us the usual immoderate intake of alcohol. However, many cases of cirrhosis in which the alcoholic intake was slight have been presented in this room.

The high serum protein is disturbing. In cirrhosis and most liver diseases the serum protein tends to be low, both the albumin and globulin being diminished, but the albumin to a greater extent. We are taught to think at once of multiple myeloma when we see a high serum protein. Multiple myeloma occasionally involves the spleen. However, I do not know of any cases in which ascites and jaundice were also present, so I am inclined to say this patient did not have multiple myeloma.

I am told that in the early stages of cirrhosis of the liver the serum globulin can be high and that only in the later stages does it become lowered, so this finding may be confirmatory evidence of the diagnosis of cirrhosis. The interval between the onset of the ascites and death is rather short for the usual case of chronic alcoholic cirrhosis. However, cases can progress as rapidly as this. Finally there is a high red-cell count (6,400,000) and a hemoglobin of 90 per cent. These are dis-

tinctly unusual findings in cirrhosis of the liver, in which anemia is the rule. It may be the clue to the diagnosis. I should like to ask Dr. Mallory if that was repeated and still found to be high.

DR. TRACY B. MALLORY: It was done on only one occasion.

DR. HARWOOD: Perhaps I should not put too much emphasis on that point. It is possible that the patient was dehydrated and had a certain degree of hemoconcentration as a result of his inability to take fluid and as a result of his diarrhea.

The record states that the patient had a ruddy color. Ruddy color and a high red-cell count, with a spleen that seemed rather larger than one would ordinarily expect in cirrhosis, make one think seriously of the diagnosis of polycythemia vera. We know that, in polycythemia vera, thromboses in various vessels are of common occurrence, particularly in the mesenteric vessels. I have not actually heard of a case of portal thrombosis in polycythemia, but at least it is conceivable that this man had portal thrombosis of gradual onset and progression, resulting in ascites, liver damage and death. The main objection is that in portal thrombosis the signs of ascites are also accompanied by marked hematemesis and even more rapid progression than in this case. Another objection to the diagnosis of polycythemia is that the red count was not extremely high. I should feel that I was on surer ground if the red-cell count had been 8,000,000 or 9,000,000. Finally, the patient did not have any of the other signs of polycythemia, such as cyanosis, distended veins and so forth. In any event I think it is a possibility. Other conditions, such as lymphoma and carcinoma of the liver, I have also thought of and discarded, because most of the signs seem to point toward a toxic hepatitis, and I shall make that my final diagnosis and just raise the question of the possibility of polycythemia with thrombosis of the portal vein.

DR. WILLIAM B. BREED: The absence of a roentgenologist gives us a golden opportunity to talk freely about these x-ray plates. I am not convinced that these pictures show merely "curling" of the lower end of the esophagus, and I should like to have someone convince me that this does not represent varices of the lower part of the esophagus. I have had occasion to review similar pictures with the roentgenologist and from time to time have persuaded him to reverse the decision. Can anyone discuss this a little more intelligently than I can? Dr. Jones, what do you think about it? How often do you see "curling" of the lower end of the esophagus? It seems an inadequate term and it does not look like curling to me. Would you say definitely that there were no varices?

DR JONES In the left hand film there is 'curling' and no suggestion of varices. In the third film to the right there is a slight suggestion of varices. It is sometimes possible by turning the patient to bring out a change in the esophageal contour. We find varices in about 40 to 50 per cent of our cases of cirrhosis. I am sure that the absence of demonstrable varices does not rule out cirrhosis of the liver. I think at times it is important diagnostically for a roentgenologist to say there are or are not varices. The right hand film certainly shows something suggestive of varices.

DR EDWARD B. BENEDICT Extensive varices give filling defects.

DR BREED I acknowledge that they are not extensive, but I should like to give Dr Harwood support.

DR JONES He certainly has enough evidence of intrahepatic involvement from the laboratory point of view. Whether that is the whole picture, I do not know.

DR JOSEPH AUB I am beguiled by the high globulin. It is a rare finding and I wonder if sarcoid should be considered.

DR JONES I should say that hyperglobulinemia is rather the rule in liver disease, and that low serum protein is not necessarily the rule. I have recently looked up 50 cases of cirrhosis, most of the patients showed a normal total protein, and the normal figure was usually due to a high globulin. Therefore the serum protein figure by itself is not too significant. It is the albumin globulin ratio that is important. Certainly, in the vast majority of patients with cirrhosis of the liver, if there is ascites or edema, there is an elevated globulin and an inverted ratio.

DR MALLORY A few months ago we had a meeting to discuss the possibility of eliminating unnecessary laboratory tests, and the question came up whether it was worth while to do albumin globulin ratios. Dr Butler was inclined to think they were rarely significant. Would you defend that statement, Dr Butler?

DR ALLAN M. BUTLER I can attempt to. But before defending it, I should like to ask one question. I notice that this patient was a Greek, and I remember Dr John Homans presenting a Greek patient, and saying that whenever you have such a patient remember he may have lived in Greece and may have come in contact with dogs and sheep. This fellow obviously had liver disease and a high globulin, and I wonder if he had lived in Greece and whether we should be thinking of echinococcal disease.

DR MALLORY He was born in Greece. There is no statement concerning how long he had been in this country.

DR BUTLER Now to defend the statement about determining albumin globulin ratios for the duration of the war.

The albumin globulin ratio is really only a qualitative analysis. Howe,* in 1921, said that 22 per cent of sodium sulfate precipitates the globulin and leaves the albumin in solution. Actually, when you precipitate any protein by increasing the salt concentration you get a logarithmic curve. If you take serum globulin and run a precipitation curve with increasing concentrations of sodium sulfate you find that with a concentration of 22 per cent all the globulin has not been precipitated. So at that particular sulfate concentration you have only a qualitative separation of albumin and globulin as some globulin remains in solution with the albumin. The next thing that makes it qualitative is that the sodium sulfate is supersaturated at room temperature. You have to keep the reagent in an incubator at 37°C to keep the salt in solution. When the technician pipettes the sulfate solution at room temperature, sodium sulfate in varying amount crystallizes out on the pipette. The amount varies a great deal with the care of the particular technician. Thus unless analyses are done carefully there is a technical error as well as a theoretical error. These factors limit the value of the routine determination of albumin globulin ratios.

Concerning the diagnosis, I think we all know that this patient had liver disease, even without the albumin globulin ratio. If any patient has liver disease and has edema too, we can guess that he has a low albumin and maybe has a low total serum protein. This latter can be determined accurately by one of several simple procedures. If the serum protein is high and edema is present, we know that the albumin is low. We do not need to do an albumin determination. Thus in such a case the albumin globulin ratio does not help a great deal. However, it may help in the rare case when one does not know whether the liver disease is serious. There was a girl presented at medical rounds six weeks ago who, from her story, might have had ordinary catarrhal jaundice. The albumin globulin ratio, however, was 0.2. That provided one of the pieces of evidence that led us to believe that the girl had something more serious than catarrhal jaundice. I do not know what happened. Do you, Dr Jones?

DR JONES She is still critically ill.

DR BUTLER In that case the albumin globulin ratio was an important factor in appreciating the seriousness of the illness. There are such rare cases in which the ratio is helpful. But to turn around and do a ratio on every patient who has

*Howe, P. E. Use of sodium sulfate as globulin precipitant in determination of proteins in blood. *J. Biol. Chem.* 49:93-107, 1921.

liver disease and ascites, or on every nephritic patient who has albumin in the urine, is not helpful enough to justify the analysis at a time like the present when we are trying to cut down laboratory work.

DR. JONES: I am in accord with Dr. Butler. In almost every case of liver disease the diagnosis is made first and the laboratory test subsequently. I think there is justification for doing this test for prognostic purposes.

CLINICAL DIAGNOSES

Toxic cirrhosis.

Hepatoma?

DR. HARWOOD'S DIAGNOSES

Alcoholic cirrhosis.

Toxic hepatitis.

Polycythemia and portal thrombosis?

ANATOMICAL DIAGNOSES

Cirrhosis of liver, type undetermined.

Hepatoma.

PATHOLOGICAL DISCUSSION

DR. MALLORY: There is a rare type of case in which one must decide whether ascites is due to

portal obstruction or to caval obstruction. In such cases the albumin-globulin ratio may be an important differential point.

This patient was peritoneoscoped by Dr. Benedict, who found a cirrhosis of unusual nodularity. Some of the nodules were a little peculiar in color and appearance so that Dr. Benedict suspected the possibility of tumor; however, he was unable to make a definite diagnosis. A biopsy of one of the nodules showed a hepatoma. Not long ago we had another case of hepatoma which had grown up the hepatic vein, as this tumor characteristically does, to form a tumor thrombus in the cava. In that man there was severe ascites in spite of a normal serum protein and a nearly normal albumin-globulin ratio. I thought the presence of a normal albumin-globulin ratio might have led one to suspect caval thrombosis by pointing toward a mechanical reason for the anasarca. In this case we have no evidence whether or not the cava was obstructed.

DR. HARWOOD: Were there any esophageal varices?

DR. MALLORY: We do not know; permission for an autopsy was not obtained.

MENINGOCOCCAL INFECTIONS

SINCE cerebrospinal fever was first recognized in 1805 this disease has been known to occur almost constantly in a sporadic form and has assumed epidemic proportions at irregular intervals. It has flourished particularly during wartime both in the military and in the civilian population. Unlike such diseases as influenza, the outbreaks of meningitis are not explosive in their appearance and do not affect a large number of people. Rather, they begin insidiously, usually increase gradually and persist for several months and often for years, but never have a high attack rate. In England during World War I there were 300 cases in 1914, 2343 cases in 1915, 1278 cases in 1916 and 1395 cases

in 1917. The case fatality rate during these years averaged about 65 per cent. In the United States Army during these years there were 5939 cases, with a mortality of about 40 per cent.

The present war has seen an even greater increase in the number of cases of this disease in Britain, where a total of 12,500 cases occurred during 1940. There has also been a marked increase in the occurrence of this disease in Canada, particularly in Nova Scotia, and, more recently, many cases have been reported in this country, particularly in New England and in neighboring states. Even greater numbers of cases are to be expected in the near future.

Compared with previous outbreaks, the present one shows several striking differences, which should be borne in mind in view of the serious attitude that health officers and the general population assume toward this disease. In addition to the low incidence of meningococcal meningitis both in the general population and among the military personnel, the case fatality rate is now surprisingly low. In Britain less than 10 per cent of all the cases occurring in the general population end fatally. In most large series of cases that have been reported, particularly those derived mainly from military sources, the mortality is more nearly 5 per cent. Young infants and aged persons still account for the greatest number of the deaths among civilians. In this country it is to be expected that less than 3 per cent of the cases occurring in army camps and less than 10 per cent of those occurring among the civil population will end fatally.

The great difference in mortality is, of course, due to the marked effectiveness of the sulfonamide drugs. Sulfadiazine is now usually recommended as the drug of choice but any of the other widely accepted sulfonamides, namely, sulfanilamide, sulfapyridine and sulfathiazole, are also effective. For the most favorable results these drugs must be given as early as possible in the course of the infection. In severe cases, particularly those in which the patient is already stuporous or unconscious, the first doses of drug should be given

parenterally. It may not be amiss, also, to emphasize the importance of the administration of fluids early in such cases since the dehydration resulting from lack of fluid intake and from vomiting may predispose to renal complications if the sulfonamide derivatives are given intravenously. Early diagnosis and early and intensive treatment are therefore highly important.

Another encouraging feature of the cases that have occurred recently is the almost complete absence of serious crippling complications in patients who are properly treated. This is in striking contrast to the high incidence of total deafness and blindness among those who survived attacks of cerebrospinal fever in previous outbreaks.

Finally, the present-day treatment is much simpler than before.* Lumbar puncture is now performed only for diagnosis or for the evaluation of the progress of therapy. Intraspinal injections of serum, with the severe complications resulting from their use, have now been completely and, it is hoped, permanently abandoned. Antimeningococcus serums, if given at all, are used only intravenously or intramuscularly in severe cases or when the disease fails to respond to chemotherapy alone. Most British physicians have completely abandoned the use of serums, but this may be due, in large measure, to expediency as well as to the excellent results obtained without them.

Several epidemiologic features are worth stressing. During periods when cases of meningococcal meningitis are prevalent there are numerous carriers of epidemic strains, particularly among the exposed population. In closed units, as in military barracks or even larger outfits, as many as 50 or even 75 per cent of persons may harbor meningococci in the nasopharynx without apparent infection. The factors underlying susceptibility to infection are not known.

There are, however, cases of meningococcemia without meningitis, which should be recognized and treated early since, if they remain untreated, the patients may develop meningitis. Such cases

are, of course, most prevalent in epidemic periods. All persons having unexplained chills, petechial or purpuric rashes and joint pains or swellings accompanied by intermittent fever and headache should be suspected of having meningococcal infections. In some cases the symptoms are entirely respiratory and nowadays are likely to be attributed to atypical or virus pneumonia. Whenever possible, blood cultures should be made during the febrile phase and sulfonamide therapy should be given early.

During every epidemic there are a small percentage of severe and fulminating cases, usually with extensive purpuric eruptions. Some of these patients, today, fail to respond to intensive therapy. Such cases will probably comprise most of the deaths unless new methods are discovered for treating these patients more effectively.

With regard to prophylaxis, there seems little reason to advocate any large-scale adventures in this field. In small, compact and self-contained military units where action is anticipated soon after a case appears or after a large number of carriers are discovered it may be possible to eliminate the carrier state by a short course of sulfonamide therapy. Such a procedure at present is neither warranted nor feasible for large units of the population.

It is most important to emphasize the early recognition of cases of meningitis and of the various forms of meningococcal infection in the absence of meningitis and to treat such patients early.

FLORENCE CRITTENTON LEAGUE

THE Florence Crittenton Mission, a national organization, was established sixty years ago to provide medical care and helpful guidance to the illegitimately pregnant woman, in an effort to protect society and the individual from the spread of immorality and disease. In the ensuing years "homes" have been established in sixty American cities. The Florence Crittenton League, the local chapter and the only one in New England, was founded fifty years ago. It consists of twenty-three

*Dingle, J. H., and Finland, M. Diagnosis, treatment and prevention of meningococcal meningitis: with a résumé of practical aspects of treatment of other acute bacterial meningitides. *War Med.* 2:1-58, 1942.

"circles" in and about Boston, whose members not only raise funds for the work of the League but also take an active interest in helping the girls and young women who come under its care.

The League maintains a home and hospital in Brighton, which is described in more detail elsewhere in this issue of the *Journal*, as well as the Welcome House, a protective home for girls from fourteen to sixteen years of age who have been exposed to unwholesome environments.

The phenomenon of illegitimacy is not new, nor is it confined to any race or clime. It has been recognized as both a medical and a social problem for innumerable years and has been studied from all angles by experts in many fields, but no complete solution has yet been found. Although war, curiously, has not increased the burden of the Florence Crittenton homes, proper care of the girl who must bear the burden of illegitimate motherhood still remains a problem, and all physicians should be aware of the fact that this type of assistance can be obtained in Boston and many other parts of the country.

MEDICAL EPONYM

SWIFT-ELLIS TREATMENT

This was described by Homer W. Swift (b. 1881) and Arthur W. M. Ellis (b. 1883) of the Rockefeller Institute for Medical Research, in the *New York Medical Journal* 96: 53-55, 1912

Our method is to withdraw blood after intravenous injections of salvarsan or neosalvarsan, separate the serum, and on the following day dilute it to 40 per cent with normal saline. It is then heated at 56°C for one half hour. By means of lumbar puncture, 15 cc of spinal fluid is withdrawn and then 30 cc of the diluted serum, warmed to body temperature, is slowly injected into the subarachnoid space. The foot of the bed is raised for about an hour after the treatment.

COMMITTEE ON MATERNAL WELFARE

BREECH DELIVERY: DEATH CAUSED BY TRANSECTION OF SPINAL CORD

Baby B was born to a twenty-nine-year-old primipara at full term. Labor lasted fifteen hours and terminated in a breech delivery; although details are not available, this was said to have been "easy and noninstrumental." The birth weight was 6 pounds, 2 ounces. No asphyxia or cyanosis was noted, but the infant did not move its legs and the arms were limp. The left arm regained some motion, the right remained completely flaccid. At four days there seemed to be some movement of the legs, which was thought to be voluntary. On the seventh day, a consultant noted tension of the fontanel and obtained bright blood by lumbar puncture. On the next day the child was transferred to another hospital.

On admission the infant had regained its birth weight, but was cold, apathetic and dribbling small amounts of urine and feces. The right arm was flaccid, and the left was held in partial flexion and internal rotation. The legs were slightly contracted at the knees without voluntary motion, but with automatic mass withdrawal on stimulus to the skin anywhere on their surface. Active knee jerks were obtained. No evidence of pain on pin-point stimulus was elicited anywhere below the neck, although usually such stimulus produced mass withdrawal of the legs. A slight facial asymmetry suggested paralysis on the right.

Two lumbar punctures during the week after admission produced grossly bloody fluid, which was thought to be due to trauma during the puncture. X-ray films of the spine showed no abnormality. It was thought that the infant had an injury to the spinal cord due to avulsion of the nerves of the right brachial plexus, with more or less complete transection of cord at the mid-cervical level. At first the child's temperature was distinctly subnormal; it then tended to rise and became irregular as aspiration of food and mucus, with resultant respiratory difficulty, increased. No changes occurred in the general neurologic picture, and the baby died eight weeks after birth, presumably because of aspiration pneumonia.

This cause of death was substantiated by autopsy, as was the neurologic lesion. There was avulsion of all the roots of the right brachial plexus,

with diffuse and practically complete transection of the spinal cord at the midcervical level. This injury was accompanied by a hemorrhagic infiltration of the distal portion of the cord, extravasated blood being found in decreasing amounts down to the level of the dorsal cord. No gross lesion of the brain or of its supporting structures or vascular supply was encountered.

DEATHS

BAILEY—WILLIAM T. BAILEY, M.D., of Boston, died January 16, in his seventy-fifth year.

Dr. Bailey received his degree from Harvard Medical School in 1900. He was a member of the Massachusetts Medical Society and the American Medical Association.

HARDING—EDWARD M. HARDING, M.D., of Newton, died December 19. He was in his ninety-first year.

Dr. Harding received his degree from the College of Physicians and Surgeons, New York, in 1874. At one time he served as second assistant physician at the Danvers State Hospital. He was a member of the Massachusetts Medical Society and the American Medical Association.

PHILBRICK—ROSCOE H. PHILBRICK, M.D., of New Orleans, Louisiana, died recently. He was in his sixty-third year.

Dr. Philbrick received his degree from Harvard Medical School in 1904. He was a member of the Massachusetts Medical Society and the American Medical Association.

TEMPLE—WILLIAM F. TEMPLE, M.D., of Boston, died December 25. He was in his fifty-sixth year.

Dr. Temple received his degree from the Harvard Medical School in 1911. He was past president of the Boston Society of Anesthetists. He served on the staff of the Massachusetts Women's Hospital. He was a member of the Massachusetts Medical Society and the American Medical Association.

MISCELLANY

NOTE

The commencement exercises of Middlesex University were held at New England Mutual Hall, Boston, on February 19. The degree of Doctor of Medicine was conferred on seventy-one successful candidates. Under the accelerated wartime program, instruction in the medical school will be resumed on March 17.

CORRESPONDENCE

FLORENCE CRITTENTON LEAGUE

To the Editor: May I call the attention of your readers to the facilities of our maternity home and hospital for the care of illegitimately pregnant girls and their babies.

The Florence Crittenton League maintains an ideal institution for the care of unmarried mothers—a unit home on the cottage plan with adequate hospital facilities surrounded with sufficient space for privacy to ourselves and to our neighbors. We also give expert care to girls who have the double misfortune of facing motherhood out of wedlock and of being afflicted with venereal disease. The physicians and social workers on the staff are experienced, and the Board of Directors is firmly convinced that the care rendered by the institution is unequaled. Hence, the Board is anxious to inform every community in New England, particularly in Massachusetts, that the maternity home and hospital exists and that we are prepared to help to the best of our ability the people of any community in matters connected with the problem of unmarried mothers.

The Florence Crittenton Home and Hospital, located at 10 Perthshire Road (Oak Square), Brighton, is the only institution of the Florence Crittenton Mission in New England. It offers prenatal, natal and postnatal care, and provides the following: cheery and comfortable rooms and dormitories for 23 expectant mothers; a hospital department including 21 beds with dental, operating-room and delivery-room suites; 33 cribs in sunny and well-ventilated nurseries and a completely equipped isolation unit consisting of 6 beds, a delivery room and a 6-crib nursery for the care of venereal-disease cases; expert medical, obstetric, pediatric and dental care in co-operation with the Boston Lying-in Hospital, Massachusetts General Hospital, Harvard Medical School and Forsyth Dental Infirmary; a large, sunny and airy 10-bed dormitory for convalescent mothers; a large, comfortably furnished living room for all classwork and recreation, with an adjacent well-equipped library; a fittingly furnished chancel adjoining the assembly room, which is opened for all devotional services; a social-service department with two trained workers, who help each girl and her family in making plans for her baby and her return to the community; and training under experienced workers in all household arts (cooking, nutrition, sewing and dressmaking), English, Red Cross home nursing, leather and metal tooling, and religious education. The charges are \$7 per week for board and \$30 for confinement, which are less than one third of the cost of the average case.

Applications should be made to the Superintendent, 10 Perthshire Road, Brighton, Massachusetts (STadium 7600). If a girl is refused admission, other sources of care are advised and she is followed by the case worker until plans are completed.

Our girls live with us for an average of five months. The mental, moral and physical care necessary for rehabilitation is obtained through a normal family life, which many of them have never known. Wholesome recreation is a vital part of our program, and includes dramatics, current events, reading and discussions, as well as special events for all holidays. Much follow-up work is done by the two case workers in helping the girls in their readjustments to the community and to the care of their babies. Such service is given to every girl as long as she needs help, and many of these friendly relations continue for indefinite periods.

CLARENCE R. PRESTON, *General Secretary*

NUMBER 11

TOXIC DUSTS, FUMES AND GASES IN INDUSTRY*

GEORGE E. MORRIS, M.D.†

BOSTON

DURING the year 1941, the Massachusetts Division of Occupational Hygiene was called on to furnish information concerning one hundred and twenty-four different industrial poisons,¹ receiving 1206 inquiries. Eighty per cent of these inquiries concerned the poisonous nature of the dusts, fumes and gases. Thus today my discussion concerns by far the greater part of the work done by this division.

Before taking up the industrial poisons in particular, it may be well briefly to discuss the avenues by which these substances get into the body. There are three main paths of entry, which in order of importance are the bronchopulmonary tree, the skin and the intestinal tract. It is to be emphasized that most industrial poisons enter the body through the lung fields in the form of vapors, gases or dust particles. Relatively few (mercury, nitroglycerin, nitrobenzene, tetraethyl lead, trinitrotoluene, the cyanides and possibly methyl alcohol) are absorbed by way of the skin, and fewer still by way of the gastrointestinal tract. Radium, manganese and cadmium are the chief ones admitted by the last method.

Not all people are equally susceptible to industrial poisons, for it is recognized that the young and the old are more prone to poisoning than are the middle-aged. Women are more susceptible than men, and pregnant women more than non-pregnant ones. People with heart disease usually react poorly to such agents as lead, nitrites, nitrates and the chlorinated hydrocarbons. Those with kidney disease are susceptible to poisoning by the heavy metals. Those with anemia do poorly when exposed to aromatic compounds. Alcohol addicts are in general poor risks.

So far as skin irritation is concerned, it can be said that colored skin is more resistant than white skin. Those with excessively oily skin often de-

velop dermatitis when exposed to cutting oils, waxes and substances soluble in fats, such as trinitrotoluene and tetryl. Those with dry skin are prone to develop dermatitis from solvents or powders.²

METALLIC DUSTS AND FUMES

Lead

The greatest amount of work done on any poison was carried out on lead. All physicians are acquainted with lead poisoning as it occurs in babies and in painters. However, from our records, lead poisoning is not considered in the differential diagnosis by physicians when they examine foundry workers, although such workers are almost invariably found to have abnormal amounts of lead in their urine. Lead is also a hazard in battery-room workers, junk-yard workers, those doing large amounts of lead burning or soldering and those engaged in salvage operations such as the cutting up of lead-painted steel structures.

Like most of the toxic substances that I shall discuss, lead is taken into the system mainly by inhalation. Only rarely is a case of poisoning by way of the gastrointestinal tract seen, and still less frequently does a case from skin absorption occur (tetraethyl lead is probably the only lead compound that is appreciably absorbed through the skin). Palsy, encephalopathy, arthralgia and colic³ are the four features that most textbooks require for a diagnosis of lead poisoning, but Kehoe⁴ found that in 30 patients with proved lead poisoning, only 1 had palsy and only 2 had encephalopathy. Twenty-one had arthralgia and 24 had colic. Thus palsy and encephalopathy can be dropped from discussion as diagnostic criteria. They are too infrequent to be of any value in diagnosis. Weakness, weight loss, constipation, abdominal pain, lead line and extensor weakness of the wrists are better criteria. Stippling of the red cells has not in my experience been found frequently enough to be of any value as a diagnostic aid.

*Read at the Postgraduate Institute, Massachusetts Medical Society, Boston, November 7, 1942.

†Physician, Division of Occupational Hygiene, Massachusetts Department of Labor and Industries; associate dermatologist, Boston City Hospital.

The Division of Occupational Hygiene has recently made 60 urinary lead determinations on girls engaged in manufacturing electrical products. These girls cut, grind and polish a plastic that contains an appreciable amount of lead. On casual inspection one would say that this process was not at all hazardous. Yet of the 60 urines analyzed, 35, or 58 per cent, showed abnormal amounts of lead. A complete study of these subjects is now being undertaken. It is not claimed that they have lead poisoning, but they are of interest because they are excreting and so must be absorbing abnormal amounts of lead. Since industrial medicine is primarily preventive medicine, the absorption and excretion of lead by workers before they show the signs and symptoms of disease are of great concern.

Recently I was called to a hospital outpatient department to see a man who complained of loss of appetite, abdominal pain, constipation and weakness of six years' duration. Gastrointestinal x-ray examination in 1936, 1939 and 1942 had shown duodenal spasm, but no ulcer. The patient proved to be a molder in a near-by foundry. In June, 1942, we had done air analyses at this foundry, and at that time the air contained lead far in excess of the maximum allowable concentration, which is 1.5 mg. per 10 cubic meters of air.⁵ A twenty-four-hour urine specimen of this foundry molder showed an excretion of 0.36 mg. of lead per liter. This is over four times the normal excretion (0.08 mg.). Here, then, was a man with a definite exposure, proved by analysis of the air which he breathed at work, symptoms referable to the gastrointestinal tract, x-ray findings of duodenal spasm and an abnormal excretion of urinary lead. It is not improbable that he had lead poisoning, and had had the same condition intermittently since 1936, though no such diagnosis appeared on his record.

A word should be said about the collection of urine in these workers. To do adequate lead determinations, a twenty-four-hour specimen is desirable, and one must be certain that the urine is collected in a container that has been washed with distilled, lead-free water. The patient must be instructed not to contaminate the urine with lead, for even small amounts introduced by accident will cause a wide error in the determination.

Antimony

The mention of lead automatically brings antimony to mind, for the two are extensively used in printers' type. Antimony is a metal that expands when it cools, and thus helps to maintain the size of the type. It is also employed in the

manufacture of storage-battery grids and of red-rubber compounds. Antimony salts have been used in the making of primer caps, and it is possible that they will be used again for this purpose. When antimony dust gets onto the skin it causes an eczematized dermatitis or a folliculitis. When inhaled or ingested it causes a metallic taste in the mouth, stomatitis, loss of appetite, nausea, vomiting, diarrhea, abdominal cramps and loosening of the teeth.⁶ These toxic symptoms are similar to those seen after the administration of tartar emetic or after the injection of antimony in the treatment of granuloma inguinale.

Antimony is often found mixed with arsenic, and in cases of poisoning it is difficult for the physician to decide which of these is the toxic agent. Arsenic poisoning need not be discussed here, since industrial poisoning from it differs very little from that occurring after the injection of antisyphilitic arsenicals.

Mercury

Mercury is used in the manufacture of explosives and of scientific apparatus. It is one of the few poisons that can be absorbed through the skin, as occurs in the mercury rubs given in the treatment of syphilis. Mercury is liquid at room temperature and volatilizes at 40°F. Thus fumes are found wherever the metal is left in open receptacles.

Symptoms of industrial mercury poisoning differ slightly from those seen when mercury is administered by injection or inunction. With the latter type of poisoning, there are a metallic taste in the mouth, stomatitis, a blue line along the gums, loss of appetite and diarrhea. In industrial poisoning, however, one also sees mental and neurologic manifestations such as timidity, discouragement, depression, insomnia, irritability and anxiety.⁷ Muscle tremors are frequent, at first fine but later becoming coarse. Normally no mercury is found in the urine, and over 0.25 mg. per liter is considered hazardous.⁸ Recently we made determinations on the urinary mercury content of 4 laboratory technicians who engaged in determining blood carbon dioxide and pH values. The mercury of the apparatus had been carelessly handled, and much of it had fallen onto the floor and into cracks in the tables and chairs. The workers were thus constantly inhaling mercury fumes emanating from the floor, chairs and tables. They were also absorbing mercury through the skin, for they were accustomed to play with the little mercury globules as they sat at the desks reading or writing reports. The respective urines of these girls showed 0.13, 0.19, 0.26 and 0.55 mg. of mer-

cury per liter. Thus it can be seen that even so small an amount as that spilled on the floor or on the tables in a technical laboratory can be hazardous. No symptoms of mercury poisoning had occurred in any of these subjects, but again the problem is to prevent such poisoning.

Manganese

Another metal of importance is manganese, which is used in alloys, dry batteries, silver solders and foundry work. It causes poisoning in a relatively short time, and cases have occurred after only three or four months of exposure. When any worker presents himself with a picture of multiple sclerosis, the diagnosis of manganese poisoning should be kept in mind, for the two diseases are clinically much alike. Such findings as languor, sleepiness, masklike facies, economical speech, cramps in the muscles of the legs, hyperreflexia, ankle and patellar clonus, retropulsion, propulsion and a slapping gait with a wide base are of common occurrence in both conditions. However, in manganese poisoning there are no eyeground changes, such as bitemporal pallor, and no spinal-fluid abnormalities. Poisoning is usually progressive and leads to disabling paralyses and permanent invalidism, but no shortening of life occurs.

Magnesium

This metal is used in foundry work, in aircraft manufacture and in the making of explosives. It is not a serious poison but causes a specific skin lesion, for when small particles penetrate the skin, a chemical reaction occurs and a specific type of foreign-body granuloma develops.⁹ Should much of the dust get into the mouth, it is probable that magnesium would act like other magnesium compounds, such as magnesium sulfate and magnesium hydroxide, causing purging and abdominal cramps.

Radium

Because of the sudden demand for radium-painted dials for airplanes, many workers are being exposed to the effects of radium. The dial-painters and the men who install the dials in instrument boards or work in the stock rooms where the dials are stored are equally exposed. An otherwise excellent book on industrial medicine³ casually dismisses radium poisoning by stating that its prevention has been shown to be a relatively simple matter, and refers the reader to a bulletin issued by the United States Bureau of Standards (Handbook H-27). On the contrary, it has recently been shown that, despite the finest ventilating equipment and the most meticulous workroom supervision, over a period of one year 3 of 100 girls working in a model radium dial-painting plant stored more

radium in their systems than is thought to be safe.^{10*} This safety value is probably in the vicinity of 0.1 microgm.¹¹ Radium poisoning was well known after World War I, when several radium dial-painters a few years after exposure developed osteitis, jaw necrosis, destruction of the bone marrow, anemia and sarcoma.¹²

Since the body cannot differentiate radium from calcium after absorption, much of the radium is excreted, but part of it is stored in the bones, where it bombards the marrow with alpha, beta and gamma particles. Such radiation at first stimulates the blood-forming tissues, but later fibrotic replacement occurs, and still later malignant neoplastic disease is prone to develop. It has been suggested that workers in this field be maintained on an adequate calcium, phosphorus and vitamin D diet for at least a month before going to work. In this way, much of the initial deposition of radium in the bones can be prevented.

It is to be remembered that radon differs from radium in that it is a gas and is taken in only by the bronchopulmonary tree. No absorption is thought to occur. Radon bombards the alveolar cells with radioactive emanations so that after many years, pulmonary carcinoma is apt to occur. The maximum permissible radon air concentration recommended in Massachusetts is 10^{-11} curies per liter.¹³

Fume Fever

Any of the heavy metals when in fume form can produce the syndrome known as metal-fume fever.¹⁴ Originally, it was believed that only zinc fumes caused this syndrome, but of late years it has become known that the fumes of lead, magnesium, and other heavy metals do so as well. The symptoms are thought to be due to the absorption of the foreign protein formed when the metal fumes come in contact with the alveolar cells and cause their necrosis. Some four to eight hours after exposure, the worker notices dryness in the throat, pains in the muscles and joints, weakness, chills and fever. The diagnosis of grippe or incipient pneumonia is often made on these workers. This syndrome is commoner in cold weather and on Mondays or after a day away from work or a vacation. The continued inhalation of the fumes seems to confer some immunity which is lost when the subject remains away from work for over thirty-six hours. No permanent disability has yet occurred from such inhalation, but it is to be remembered that if the fumes are from one of the poisonous metals, serious sequelae may result.

GASES AND VAPORS

By far the most important toxic gases and vapors are the volatile solvents, which now comprise

*This radium was subsequently eliminated by suitable treatment.

over three hundred and fifty different substances. The toxic gases and vapors are divided into asphyxiants, irritants and metabolic poisons, including the anesthetics and the volatile solvents.

Asphyxiants

The asphyxiants may be classified as physical and chemical. The former act by replacing oxygen in the air. Such agents are hydrogen, methane, ethylene and nitrous oxide. They are of relatively little importance in industry. The chemical asphyxiants act in either of two ways, preventing the formation of oxyhemoglobin or preventing the utilization of oxygen by the tissues.¹⁵ Carbon monoxide, which inhibits the formation of oxyhemoglobin, has been called "probably the most important industrial poison." This may be the case in other states, but in Massachusetts carbon monoxide ranks far below silica, lead and the organic solvents as an industrial hazard. It is formed wherever organic material is burned in the presence of insufficient oxygen. It has an affinity for hemoglobin three hundred times that of oxygen. Thus when it is inhaled, carbon-monoxide hemoglobin forms in preference to oxyhemoglobin. The usual symptoms seen in all asphyxiation cases are present, namely, tightness across the head, headache, throbbing in the temples, weakness, dizziness, dimness of vision, nausea, vomiting, collapse and coma. The worker should be removed from the contaminated area and given oxygen and carbon dioxide by inhalation.

The chief chemical asphyxiants that prevent the utilization of oxygen by the tissues are hydrocyanic acid and its derivatives—cyanogen, acetonitrile and vinyl cyanide.¹⁶ The last is important, for it is now being extensively used as a solvent in the synthetic-rubber industry. Many of these cyanide compounds can be absorbed through the skin. Treatment of cyanide poisoning consists in the formation of methemoglobin, for cyanide has an affinity for this substance. Methemoglobin can be formed by the administration of sodium nitrite by mouth or by the inhalation of amyl nitrite. Methylene blue in doses of 1 to 2 mg. per kilogram of body weight may be given intravenously for this purpose.⁶

Irritants

The second great group of gases is known as the irritants. These cause inflammation and sometimes necrosis of the tissues with which they come in contact. Some give off a warning odor, but this is not a reliable sign, for the olfactory sense readily becomes fatigued or accustomed to the odor, and so fails to warn of the presence of the irritant. Such irritants include the fumes of acids, ammonia and aldehydes.

Since in general they produce no systemic effects, a few principles will help to keep their action in mind. The first point to be remembered is that the part of the respiratory tract affected varies with the solubility of the inhaled irritant in water; that is, the more soluble the irritant in water, the more readily will it dissolve in the moisture of the upper respiratory tract, with consequent irritation of the nose and trachea. As a result, the worker tends to avoid the area where the fumes are present. The less soluble irritants do not dissolve in the nose and throat, and so penetrate deeper into the bronchopulmonary tree. Since there is less irritation of the nose and the throat, the contaminated area is not avoided and poisoning is apt to ensue. Being only slowly soluble, the effects of these irritants are delayed in onset. Thus eight, twelve or twenty-four hours after exposure, dry cough, tightness of the chest, pulmonary edema, hemoptysis and even death may occur.

The oxides of nitrogen are relatively insoluble gases. Thus the effects of their inhalation are latent, and symptoms do not occur until eight to twelve hours after exposure. Nitrogen oxide fumes are apt to be present wherever nitrates are being used. Nitrates are ingredients of explosives, dyes and plastics and are employed as metal-cleaners.

In contrast to nitrous fumes, chlorine and hydrochloric acid, sulfur dioxide and sulfuric acid are extremely soluble and cause immediate irritating action, mainly restricted to the upper respiratory tract. But chlorine and sulfur dioxide, being gases, also invade the alveolar spaces and so may cause pulmonary edema as well. Other fumes of recent interest are those of the fluorides, now being used as coating agents on welding rods. When such rods are melted, fluoride fumes are evolved, and if these are inhaled in strong concentrations, irritation and ulceration of the upper nasal passages occur, and nosebleed is frequent. Fluorine acts like radium or calcium when it enters the system, and is deposited in the bones in a similar manner.¹⁷ Here it sets up a chronic fibrotic reaction, and a proliferated osteitis occurs. The rate of deposition of fluorine in the bones seems to equal the amount that is being put out in the urine. Ten determinations of fluorides in the urine have been made during the past six months at the Division of Occupational Hygiene. Two of them were over the proposed normal limit of 3 mg. per liter¹⁸; one of the subjects worked in a foundry and the other was a welder.

The last of the irritant gases and vapors to be considered are the aldehydes. Formaldehyde is used in the manufacture of artificial resins and disinfectants. Acrolein is commonly found in proc-

esses where fatty substances are being heated. The aldehydes, being soluble, are extremely irritant to the upper respiratory tract.¹⁰ In high concentrations they are anesthetic.

Metabolic Poisons

Alcohols. Of the aliphatic alcohols, methyl alcohol (wood alcohol) is the most important.²⁰ It is used as a solvent in varnishes, shellacs, lacquers, gums, dyes, rubber cement and plastics, and is employed in dry cleaning. Methyl alcohol, or methanol, unlike other alcohols, is metabolized slowly and so has a cumulative effect. It enters the system principally by inhalation, but poisoning has occurred by ingestion and probably by absorption through the skin. Some people are markedly susceptible to this poison. Exposure to fumes of methyl alcohol causes burning of the eyes, respiratory tract and skin; followed by headache, fatigue, depression, staggering gait, loss of appetite, nausea, vomiting, abdominal pain and diarrhea. In severer cases, cyanosis, confusion, paralysis and visual hallucinations are apt to occur. Methyl alcohol has a specific toxic effect on the optic nerve; any worker who complains of visual disturbance in addition to gastrointestinal symptoms must be questioned closely concerning his occupation.

Other alcohols are not used in industry to any great extent, but in general it can be said that, within certain limits, as the molecular weight increases the narcotic and skin-irritating properties also increase. Thus amyl alcohol, with the exception of methyl alcohol, is the most toxic of the commonly used alcohols. However, since the volatility decreases as the molecular weight increases, there is less chance of exposure to fumes of the higher alcohols; as a result, only a few cases of industrial poisoning from them have occurred.

Chlorinated hydrocarbons. Of the chlorinated hydrocarbons, only four are of interest here.²¹ They are chloroform, carbon tetrachloride, trichlorethylene and tetrachlorethane. The chlorinated hydrocarbons are among the most poisonous of the solvents. They are liver and metabolic poisons and have a marked effect on the nervous system. They cause optic neuritis and atrophy in susceptible subjects, and are also cardiac depressants. In general, the toxicity increases as the molecular weight increases and as the number of chlorine atoms increases.

Carbon tetrachloride has the same structural formula as chloroform, the toxic symptoms of which are well known, except that another chlorine atom has been added.²² This single structural change makes it less anesthetic than chloroform but more toxic to the liver, kidney, heart and brain. It is now little used in industry, but cases of poisoning

from it still occur quite commonly. It may affect the respiratory tract, the gastrointestinal tract, the skin, the liver or the brain. Respiratory symptoms occur when moderate concentrations are inhaled: these include cough, bronchitis, bronchopneumonia, pleuritis, hydrothorax, hemothorax and pulmonary hemorrhage. The gastrointestinal symptoms are anorexia, nausea and vomiting. Carbon tetrachloride is a hyperosmic stimulant; that is, nausea and vomiting may occur without any other toxic symptoms. The liver is often severely inflamed, and there may be yellow atrophy in cases of acute exposure, or cirrhosis in chronic poisoning. Carbon tetrachloride is a depressant and narcotic of the central nervous system. There is often acidosis and a low blood-calcium level in acute poisoning. The acidosis has been ascribed to the absorption of hydrochloric acid, but it may be due to disturbance of the oxidative function of the liver.

Trichlorethylene,²³ the third important chlorinated hydrocarbon, is an unsaturated compound that is noninflammable and a relatively good solvent. It is less irritating to the respiratory tract, less injurious to the liver and less narcotic than most of the other chlorinated hydrocarbons. In low concentrations it creates a pleasant feeling of intoxication, with unsteadiness, confusion, mental dullness, anorexia, nausea, vomiting and fatigue. Constant exposure has led to the development of addiction and has caused retrobulbar neuritis and polyneuritis. In high concentrations this substance is narcotic.

Tetrachlorethane²³ is the only other halogenated saturated hydrocarbon of importance. It is used in lacquers and varnishes. Having a high molecular weight and four chlorine atoms, it may be expected to have marked toxic properties. As a matter of fact, it is probably the most poisonous of the chlorinated hydrocarbons, possessing severe narcotic properties and causing acute yellow atrophy of the liver and a fatty change in the heart and pancreas.

Other organic substances. There are a few other organic substances in use that are rapidly becoming of increasing importance.

One of these is methyl ethyl ketone (butanone).²⁴ The recent development of synthetic methods of preparation has made it available in commercial quantities, and it is being used in lacquers, cements, varnishes and paint removers and in the manufacture of drugs. It is an irritant to the conjunctiva and nasal mucosa, but as yet no cases of industrial poisoning from it have occurred. In high concentrations it will probably prove to be a pulmonary irritant and a narcotic.

The glycols are aliphatic hydrocarbons with two hydroxyl groups. They are good solvents and are of low volatility. In general, they are narcotic if

inhaled in high concentration. They cause serious kidney damage if ingested.

The cellosolves are ethers that are derived from the glycols.²⁵ They also contain an alcohol radical and retain many of the characteristics of ethers and alcohols. They are irritants and depressants of the central nervous system. They are excellent solvents for cellulose, natural resins, acetate lacquers and enamels. Chronic exposure causes headache, dizziness, stomach disorders, psychotic symptoms, mental retardation and polyneuritis. Anemia, thrombocytopenia and granulocytopenia have been reported from exposure to these solvents.

Aromatic compounds. Last come the aromatic compounds, comprising benzene and its derivatives.^{15, 21} Benzene is an excellent solvent for rubber, cellulose, gums, resins, fats and oils, and is used as an ingredient of many paint removers. It is an anesthetic and is a depressant to all the elements of the bone marrow. Chronic exposure causes anemia, leukopenia and thrombocytopenia. Benzene poisoning can be suspected when the white-cell count is persistently under 5000 and the red-cell count under 4,000,000 in a person exposed to benzene vapors. Change in the urine sulfate partition is one of the best diagnostic criteria for benzene exposure.²⁶ Normally 90 per cent of the urine sulfate is in inorganic form and 10 per cent ethereal. After exposure to benzene, the percentage of ethereal sulfate tends to increase. When it becomes 50 per cent of the total, benzol poisoning can be suspected.

The introduction of methyl groups to the benzene ring gives toluene and xylene. There is no unanimity of opinion regarding the toxicity of these substances, but it is generally thought that they are more narcotic but less hemotoxic than benzol. In any event, they are less apt to be found in toxic concentrations in industrial plants, and so have been recommended as solvents in place of benzol for many purposes.

By the introduction of an amino group into the benzene ring, aniline is formed. It is used as an intermediate in the manufacture of drugs, dyes, resins, inks and rubber accelerators. Aniline and its immediate homologues affect the blood and the central nervous system. The main portal of entry is by way of the skin, and only a few cases of poisoning have occurred by inhalation. In acute poisoning, one sees weakness, somnolence, headache, vertigo, convulsions and even death.²⁷ In chronic poisoning, the most striking effect is on the blood. There is hemolysis of the red cells, as well as the formation of methemoglobin. Cyanosis is commonly seen in workers with aniline. The white cells ordinarily show little change, but there may

be depression of all the bone-marrow elements, as in benzene poisoning. Bladder tumors have been reported.

The toxicity of the aminobenzenes can be best remembered by recalling that the sulfonamides are among them. Acetanilid is another aniline derivative. These drugs cause confusion, loss of appetite, nausea, vomiting, methemoglobin formation and many other well-known toxic signs and symptoms. It is therefore unnecessary to memorize the symptoms and signs of aniline poisoning, for the picture is similar to that seen in poisoning from the sulfonamides and the antipyrine group of drugs.

The nitrobenzenes are also hemolytic poisons and depressants of the central nervous system.²³ Like aniline, they can be absorbed through the skin. They are extensively used in the manufacture of explosives.

Trinitrotoluene, one of the nitrated aromatic compounds, is also absorbed through the skin. It has been reported to have caused cyanosis, methemoglobinemia, chronic gastritis, anemia and jaundice. It causes yellow discoloration of the skin hair and nails and is a skin irritant.

The chlorobenzenes are extensively used in moth balls and also in anti-moth sprays for fur and other clothing. The chlorobenzenes are probably more narcotic than benzene but less hemotoxic. Jaundice, kidney damage and methemoglobinemia have been reported from exposure to them. Since some of the chlorobenzenes are solids, one should inquire concerning the solvent used in commercial liquid preparations; chloroform, carbon tetrachloride, benzol and carbon disulfide are frequently employed and are toxic in their own right.

* * *

This concludes the discussion of the common toxic dusts, fumes and gases encountered in industrial practice. With the increasing employment of inexperienced young and old workers, it is imperative that all physicians be on the alert for illness due to industrial exposure, for only by the early diagnosis of such illness can the men at the front lines be supplied with the necessities of an airtight war.

THE CONDITIONED REFLEX AS A TREATMENT FOR ABNORMAL DRINKING

Its Principle, Technique and Success

JOSEPH THIMANN, M.D.*

BOSTON

NO OTHER disease is so widely spread or so detrimental from the medical, sociologic, legal, economic or any other point of view as is chronic alcoholism. The experience that will power and good intentions on the part of the unfortunate alcoholic patient are in most cases as inefficient as a pledge led physicians, and especially psychiatrists, to look for another, more promising cure. Unfortunately, all the usual types of therapy—hospitalization (voluntary or by commitment), "alcoholic farms," sedation, vitamins, gold injections, amphetamine (Benzedrine) and even psychotherapy, inclusive of psychoanalysis—have proved to be of help in not more than 15 to 25 per cent of the cases so treated. A proportion of cures of 50 to 75 per cent claimed for any form of therapy can easily be reduced to a more accurate figure by asking what period of total abstinence without relapses is meant by "cure," and how many records of patients can be produced.

Everyone is familiar with the fact that the ingestion of tainted food causes sickness, disgust and abhorrence for this kind of food for a long time. The sight, smell, taste or even thought of it makes one sick. Moreover, the inability to take good, untainted food resembling it in appearance, smell or taste may last for weeks, months or years. A physiologist would describe the mechanism of this phenomenon thus:

Clostridium botulinum is the unconditioned stimulus causing the unconditioned reflex response of sickness and vomiting. The meat or fish is the conditioned stimulus that is able to elicit later the conditioned reflex of vomiting even after omission of its real, original cause.

By substituting for the toxin (unconditioned stimulus) an emetic and for meat (conditioned stimulus) an alcoholic beverage, more or less at the same time there will be developed, after a period of treating or conditioning, the conditioned reflex of emesis whenever alcohol is seen, smelled or tasted. Simple as this principle sounds, it is difficult or impossible to accomplish the desired results without knowledge of all the peculiar characteristics of a conditioned reflex. That is why so many attempted forms of treatment based on this idea have been unsuccessful.

The earliest scientific attempt at treating alcoholic patients by using an emetic as an unconditioned stimulus was made in 1933 by two Russian physicians, Sluchevsky and Friken.¹ The emetic used by them was apomorphine. Seven patients were treated. On only one of them, however, were continued observations made. This patient was reported as having developed the conditioned reflex several weeks after the treatment was completed. Several therapists reported subsequently on apomorphine as the unconditioned stimulus. The number of patients in all cases was small, the largest group being 36, mentioned by Fleming,² who estimated 25 per cent of perma-

*Medical Director, Washington Hospital

nent cures. He thought, however, that the sincere co-operation of the patient was essential for success, and that almost any method of treatment would be successful with this type of patient.

There is an old treatment with a familiar name that is based on the right principle. However, it fails because of a faulty technic. In it, the emetic is added to the alcoholic drink. The alcohol is soon absorbed and the patient is partly intoxicated—that is, narcotized—at the time when the emetic acts. Pavlov proved that no conditioned reflex can develop in a narcotized subject. Further, the emetic used in this cure has two bad complementary aftereffects: a euphoric and a hypnotic one. The result of the euphoric state is that the patient, instead of feeling sick after the treatment, feels "fine," which does not promote development of the reflex of abhorrence and nausea. The hypnotic aftereffect causes a sound sleep for several hours, with subsequent amnesia, which also is not conducive to the desired results.

Finally, however, after years of research and experimentation, the right kind of emetic (emetine), with all the desired properties and none of the disturbing ones, was selected and a careful and skilful technic was devised. Voegtlin and Lemere³⁻⁵ have practiced this treatment for six years. They use a solution of 50 gr. of emetine (an alkaloid of ipecac), 25 gr. of pilocarpine and 23 gr. of ephedrine in 40 cc. of water, 0.4 to 1.0 cc. of which is injected intramuscularly 4 to 12 minutes before a drink is given to the patient. In accurate follow-up reports on 1194 patients they give the following results⁶: 74.8 per cent of 644 patients treated for less than two years were still abstinent; 52.5 per cent of 291 patients treated from two to four years ago were still abstinent; and 51.5 per cent of 259 patients treated four or more years ago were still abstinent.

For successful conditioned-reflex therapy, all extraneous auditory, olfactory and visual stimuli must be eliminated and the conditioned stimuli emphasized.

The elimination of auditory extraneous stimuli is achieved by a soundproof treatment room and by avoiding conversation during treatment. The positive auditory stimuli are purposely exaggerated—the clinking of bottles and glasses, the gurgling sound of liquor being poured into glasses and the sounds of retching and vomiting.

Undesirable visual stimuli are all furniture and articles in the treatment room that are not essential for the treatment. The room should be painted a plain dull color and contain a comfortable chair for the patient and another for the therapist, and a bar or table with liquor bottles and glasses on the spotlighted surface.

Sundry medical supplies (syringe, emetic solution and so forth) should be on a shelf of the bar or table invisible to the patient.

Olfactory stimuli that may vitiate the treatment are odors arising from the kitchen, laboratory, medicine chest (paraldehyde) or lavatory. Conditioning olfactory stimuli are emphasized by having the patient smell of the glass before and after the drinking. As the pilocarpine used in the emetic increases the secretion of nasal mucus, the patient should be reminded to blow his nose frequently.

No food and no sedatives should be given within twelve hours before treatment. Any narcotizing agent (alcohol, barbiturates, bromides, chloral hydrate and so forth) taken after the treatment counteracts the conditioning; stimulants like amphetamine (Benzedrine) further it.

The treatment sessions are given four to seven times on successive days and repeated once after one, two, three, six, nine and twelve months during the first year.

It is well to keep in mind that the treatment should be used in common with psychotherapy and social therapy in order to eliminate the extrinsic and intrinsic factors that cause or contribute to drinking.

The results of the treatment depend largely on the selection of patients suited to this type of therapy; patients with psychopathic traits and those whose attitude lacks sincerity and co-operation are apt to be failures.

Conditioned-reflex therapy as practiced at the Washingtonian Hospital differs from the treatment employed by Voegtlin and Lemere in the formula of the emetic solution used and in the after-therapy. It was found that when pilocarpine and ephedrine were given in the amounts used in their treatment, the patients developed spasms of the urinary bladder and intestinal tract. This not only was painful, but because the treatment had to be interrupted to relieve the spasm, the mind of the patient was diverted and the conditioned-reflex therapy was thereby lessened in effect. Furthermore, probably owing to the large amount of pilocarpine used, the patient complained of blurred vision of sufficiently severe degree to make it difficult for him to read even the labels on the bottles on the treatment table. This produced in him fear of definite visual damage and again his mind was diverted from the treatment. On the other hand, the dosage of ephedrine was not sufficiently high to prevent the drop in blood pressure that emetine usually provokes. It was found that the systolic blood pressure of the majority of patients, measured the morning before treatment, is 100 or less. When emetine was superimposed on the

customary low blood pressure in the majority of chronic alcoholic patients may cause dangerous shock. For these reasons the amount of pilocarpine in the stock solution was reduced to 15 gr. and that of ephedrine increased to 30 gr. It was also found that if ephedrine was given an hour before the treatment, sometimes the effects wore off and the blood pressure fell, owing to the combined effects of the emetine and the lapse of time. For this reason it proved preferable to increase the amount of ephedrine in the solution given, rather than to administer it beforehand.

The after-therapy practiced in this hospital varies from the Voegtlin and Lemere treatment in the following particular. It is believed that psychotherapy, carried out on the traditional intellectual level and, even more important and efficacious, on the emotional level, is of great value as an adjunct to drug therapy. It was found insufficient for the patient to return at intervals of one, two, three, six, nine and twelve months for reinforcement therapy. Contact with the hospital and with the physician is inadequately maintained unless the patient sees the doctor and returns to the hospital environment at regular weekly intervals. Only by coming back frequently is the bond between the patient and the physician strengthened and the psychologic impression of both the physical and the psychical strain accompanying the conditioned-reflex treatment maintained. By supplementing the monthly periods of reinforcement by weekly visits, the patient is prevented from slipping into the delusion of the conviction that he can take a social drink without relapsing. By frequent visits, moreover, he is kept in the mental attitude of a

patient still under treatment. His approach to the reinforcement therapy thus has less psychic shock and he dreads the treatments less than would be the case if a month or more had gone by before he came to the hospital again. The patient is therefore urged to spend his week ends and other free time within the hospital for a period of several weeks and, if possible, months, in addition to returning for reinforcement treatments.

Although conditioned-reflex therapy, employing the technic described, has been in operation in this hospital for too short a period (seven months) for the results to be conclusive, the number of successful treatments is extremely gratifying. Of 43 patients treated, 27, or 63 per cent, have been entirely abstinent since treatment, which represents the longest period in their lives of freedom from drinking. It is thought that this figure shows that the treatment has been efficacious and is worthy of further trial.

SUMMARY

The use of the conditioned reflex in the treatment of chronic alcoholism is discussed, and its apparent success in a small series of cases is described.

CLINICAL NOTE

VARICELLA FOLLOWING EXPOSURE TO HERPES ZOSTER

JOSEPH GARLAND, M.D.*

BOSTON

VON BOKAY,¹ in Budapest in 1892, first made note of an apparent relation between herpes zoster and varicella; he² reported further cases in 1909. Since that time the clinical relation between the two diseases has been repeatedly, even if not frequently, noted.

Among the more recent reports is that of Blatt, Zeldes and Stein,² who in 1940 published 2 case histories from the Children's Division of the Cook County Hospital. In the first, a bedridden child in the tuberculosis ward developed herpes zoster eleven weeks after admission. Thirteen days later a contact who had had no other exposure for a year developed varicella, and thirteen days later a third child developed varicella after exposure to the second child. In the second case two children developed varicella fourteen and eighteen days after exposure to a nurse with herpes zoster. This nurse had previously had chicken pox. It is of interest that no generalized epidemic followed either of these incidents.

Weigand,³ in 1942, reported two siblings who developed typical chicken pox two weeks and four weeks respectively after exposure to a grandmother suffering from herpes zoster. Presumably the second child, with a severer infection, developed the disease as a result of contact with the first. There had been no other exposures.

In the interest of adding further presumptive evidence of an infectious phenomenon not commonly seen and not as yet universally accepted to that already accumulated, the following cases deserve brief mention.

The mother of two children, a daughter, aged 8, and a son, aged 6, first noticed soreness of the left side of her throat on January 23. By January 28 pain and swelling of the left side of the face had developed, and on January 30 a typical eruption of herpes zoster appeared in this area. She had had varicella in childhood. Fourteen days after her first symptoms had appeared, the son showed the scattered papules of an eruption that became well-defined varicella 24 hours later, and on the following day the husband and the daughter broke out with typical, moderately severe chicken pox. No known exposure to chicken pox had occurred for any of the three. The daughter had been confined to the house with a cold since the beginning of her mother's illness, and no cases had occurred in the small school group of which the son was a member.

The literature on the zoster-varicella relation was reviewed by Bruusgaard⁴ in 1932, and by Blatt, Zeldes and Stein² in 1940. As a result of the lack of exact knowledge about so many of the aspects of virus infections, there continue to exist two schools of thought concerning their relation. The dualists, represented chiefly by Comby,⁵ believe in two separate and distinct viruses as the etiologic agents of the two diseases. The monists, including von Bokay,¹ Netter and Urbain,^{6,7} Lipschutz and Kundratitz,⁸ Kundratitz,⁹ Bruusgaard⁴ and others, believe that the two infections are caused by the same virus with the faculty of undergoing mutation in regard to infectivity and tissue affinity, changing from a neurotropic form in herpes zoster to a dermatotropic form in varicella. Goldsmith¹⁰ is responsible for the statement that persons develop varicella following exposure to herpes zoster ten times more frequently than do those following exposure to varicella.

The arguments of the dualists are based on the differences between epidemiologic and immunobiologic conditions obtaining in the two diseases. Varicella, for instance, leaves a pronounced immunity, whereas not infrequently patients who have had varicella later develop herpes zoster. Varicella is a disease of childhood, whereas herpes zoster rarely attacks children, its highest incidence being in the sixth decade. Varicella is highly communicable, but herpes zoster is only slightly so. Cantor,¹¹ moreover, in twenty years on a Pacific island saw much herpes but no varicella, whereas Støren¹² had a similar experience in Norway.

The theory of monism is based not only on the clinical evidence supplied by cases of varicella apparently resulting from exposure to herpes zoster, but on considerable experimental work as well. Thus various investigators, notably Netter and Urbain,^{6,7} have demonstrated by complement-fixation tests that serums of patients with these diseases contain identical antibodies. This, of course, may be only the expression of a group reaction between closely related although nonidentical viruses, but it is a challenging observation.

It is of interest that the same complement fixation occurs with so-called "symptomatic" herpes zoster, such as that sometimes appearing after the introduction of arsenic or bismuth, or following smallpox vaccination. In these cases the reaction is probably due to the activation of a latent virus by factors acting as *agents provocateurs*. This is consistent with the property of latency apparently possessed by the viruses of herpes, both zoster and simplex.

*Instructor in pediatrics, Harvard Medical School; physician to Children's Medical Department, Massachusetts General Hospital.

Inoculation with the fluid from zoster vesicles has been reported by Lipschutz and Kundratitz⁸ and by Bruusgaard.⁴ Lipschutz and Kundratitz found that some subjects developed only local reactions, and some a generalized varicelliform eruption as well. Children who had recovered from varicella were immune to zoster inoculation (although not necessarily immune to herpes zoster in adult life), and children who had recovered from natural or experimental herpes zoster were immune to inoculation with varicella fluid; moreover, serum from subjects convalescing from herpes zoster could be used as a protection against varicella.

Examining tissues histologically, Bruusgaard found that the varicella-like lesions resulting from inoculation with herpes zoster fluid show the same microscopic picture as that of the vesicles from ordinary herpes zoster or varicella, accompanied by degeneration of the epithelial cells with vacuolation and oxyphile elements in the nuclei, and multinucleated cells.

Bruusgaard's own cases comprise five series, each series having been inoculated from a different case of herpes zoster. Eight out of a total of 18 children showed positive takes seven to nine days later. In 4 of these there was only a reaction at the site of the inoculation. In the other 4 cases a generalized exanthem indistinguishable from varicella appeared fourteen days after inoculation, in addition to the local reaction. All positive results were in children under five years of age. A considerable number of secondary cases of varicella, all comparatively mild, occurred among children exposed to the inoculated group.

It is apparent that the proponents of the theory of a single, mutable virus for herpes zoster and varicella can present strong evidence to support their claims, even if exact proof is lacking. Thus the generalized eruption of herpes generalisatus, indistinguishable from varicella, assumes special interest as the best evidence available that the neurotropic virus of herpes zoster may also show definite dermatotropism.

Zinsser,¹³ in developing the thesis that many examples exist in nature in which modifications of

virus seem to have developed spontaneously, points to the relation between herpes zoster and chicken pox as a likely one, and Sabin,¹⁴ discussing the neurotropic virus diseases of man, alludes to the strong possibility that herpes zoster and varicella may be manifestations of the same virus.

As Bruusgaard concludes:

The same difficulties arise here as are encountered in the interpretation of the reciprocal relations between the different types of other ultramicroscopic viruses, to meet which difficulties we try in the meantime to seek assistance from speculation and theories. The reasons for this, as Doerr emphasizes, are sufficiently clear, namely, the fact that none of these infective substances have been identified morphologically, and that they have not proved culturable in the laboratory.

SUMMARY

Three cases of varicella following exposure to a case of herpes zoster are reported, and the relation between varicella and herpes zoster is discussed.

MEDICAL PROGRESS

RECENT ADVANCES IN TESTOSTERONE THERAPY*

JOSEPH C. AUB, M.D.,† AND SEYMOUR S. KETY, M.D.‡

BOSTON

MUCH has been learned of the effects and therapeutic usefulness of testosterone since the previous review on this subject by one of us (J. C. A.) in 1940. Newer concepts of its physiology and wider clinical experience warrant, perhaps, another summary of the knowledge concerning this important endocrine substance.

Physiology

The history of the discovery and isolation of the male hormone has recently been well summarized.² Testosterone, first synthesized by Ruzicka and his associates,³ in 1935, is apparently identical with the hormone of the interstitial cells of the testicle. Its most striking effects, manifested naturally in the normal adolescent male or artificially by the administration of the hormone to patients with testicular deficiency, are already well known. They consist of a development of secondary sex characteristics, and a growth of the penis, scrotum, prostate and seminal vesicles; the appearance of hair on the pubis, face and other areas of the body; a deepening of the voice; and a development of the masculine behavior patterns of aggressiveness, vigor and self-confidence.

The relation of testosterone to the various endocrine organs is in need of further clarification. Like the secretions of the other peripheral endocrine glands, testosterone appears to exert a specific inhibitory action on the pituitary gland.⁴⁻⁶ In females and eunuchoid males treated with testosterone, there is a decrease in the excretion of the gonadotropic hormone of the pituitary.⁷⁻⁹ In studies on women it was found that the administration of testosterone inhibits follicle formation, ovulation and the formation of the corpus luteum in the ovary, probably through its effect on the hypophysis.⁵ These effects occur with large doses of the drug, but smaller amounts of testosterone exert a stimulating effect on the adrenal, thyroid and parathyroid glands and on the ovary as indicated

in animal experiments.¹⁰ It appears to be a not unusual occurrence that small amounts of the target glands stimulate whereas larger amounts inhibit the anterior pituitary gland.

Recent investigation has increased appreciation of the role that testosterone plays in the metabolism of the body as a whole. Many have observed an increased basal metabolic rate under the influence of testosterone,¹¹⁻¹⁶ and one group¹⁵ by showing a lowering of the respiratory quotients suggests that it may effect a greater oxidation of fats. Like other steroid hormones, testosterone has been observed to cause a decreased excretion of electrolytes and water.^{15, 17, 18} A definite retention of phosphorus and nitrogen occurs during its administration,^{12, 15-20} and to a greater degree than can be explained by the genital hypertrophy. This is taken to be an indication of a generalized increase in musculature, a view that is further strengthened by the finding of increased excretion of creatine in treated patients^{20, 21} or paralleling a rise in urinary androgen in children.²² Patients with hypogonadism treated with androgens also exhibit a marked increase in endurance and the ability to perform static and dynamic work,^{23, 24} although this effect is not produced in normal men.²¹ This is of interest inasmuch as it goes far to explain the greater musculature of the males of most species, particularly strikingly shown in the male deer during the season of testicular hypertrophy and activity. These findings of the important role that testosterone plays in nitrogen metabolism and growth of muscle and bone form one of the most promising developments of recent endocrine investigation. Their therapeutic implications have already been realized in the treatment of retarded growth, but more widespread usefulness should certainly be discovered in the near future. An unexplained lowering of glucose tolerance and a decrease in liver glycogen have been reported during the administration of methyl testosterone.^{11, 13}

Any clinician who has observed the delicate, light skin and the vasomotor instability of eunuchoid patients has been impressed with the importance of testosterone to the skin and vascular system. These clinical impressions are confirmed by studies that show a decreased excitability²⁵ and an increased velocity of blood flow¹⁵ in vessels after testosterone administration. An increased

The articles in the medical-progress series of 1941 have been published in book form (*Medical Progress Annual*, Volume III, 678 pp. Springfield, Illinois: Charles C Thomas Company, 1942. \$5.00).

permeability of the capillaries in the rat uterus and vagina has been reported.²⁶ The possibility that the sex hormones and the androgen : estrogen ratio are related to the occurrence of acne vulgaris has been discussed,^{27, 28} although their mechanism is still to be understood. The predominant occurrence of this disease in adolescent boys and the good reports with estrogens as therapy²⁹ suggest that relative increase of testicular secretion plays some part. This is confirmed by the not infrequent appearance of acne in eunuchs treated with testosterone. It is not certain that this reaction is dependent on the androgen : estrogen ratio, but it must be recalled that boys and girls excrete both 17-ketosteroids and estrogens, with only a variation in quantity to differentiate the sexes.³⁰ An interesting property of testosterone is its ability to produce a significant increase in red cells and hemoglobin in eunuchoid individuals.^{33, 31}

Methods of Administration

Few substances equal testosterone in the variety of routes whereby it may be effectively administered. The classic route—by intramuscular injection in the form of testosterone propionate in oil—still has much to recommend it. Its effects are rapid and sufficiently sustained to require only two or three injections per week. It was soon found, however, that testosterone and its derivatives, like some other steroid hormones, are absorbed through the skin, and many have advocated their administration by inunction.³²⁻³⁵ Although the dose required compares favorably with that of intramuscular injection, the type of base used has a great deal to do with the effectiveness of absorption.³⁶ In our experience this type of therapy has not been extremely successful, and neither generalized nor local effects have been spectacular.

In an attempt to effect a slow and physiologic absorption of this hormone with a minimum of inconvenience, some have used the technic of subcutaneous implantation of sterile pellets of testosterone and its derivatives, such as the propionate.^{31, 37-41} Studies of the absorption rates of such pellets demonstrate that both testosterone and the propionate ester are relatively well absorbed.^{42, 43} This confirms the clinical impression that effects may be exerted for periods of weeks to several months. Although this technic is far more economical with respect to the necessary quantity of the hormone, it has been deemed unsatisfactory by some,^{44, 45} and others have found that the implants occasionally slough⁴⁶ or become infected.⁴¹ On the whole, however, this technic has been recommended as easier than continuous injections, and some prefer it to the ingestion of tablets. It

has the advantage of a constant, rather slow, absorption rate.

The recent development of methyl testosterone offers a form of the drug that is clinically effective when taken by mouth. Except for a few dissenting voices,⁴⁵ investigators are agreed on the efficacy of this form of administration.^{14, 23, 33, 34, 40, 47-50} In our experience it works particularly well in stimulating body growth and development. There are apparently no side effects except for occasional mild gastric distress, easily relieved by alkalis. This drug is said to cause less hirsutism in the female, though we have certainly seen it develop; it produces all the other anatomic changes produced by testosterone parenterally. The only objections to the oral use of methyl testosterone are its comparative expense, since considerably more than the parenteral dosage is required, and the fact that its effects develop somewhat less rapidly. The sublingual route has been used successfully for the administration of testosterone and its derivatives.⁵¹

Indications

Diseases peculiar to males. In this group of diseases one finds the most physiologic and rational indications for testosterone therapy. Favorable and usually dramatic results are achieved with replacement therapy in all types of *adult testicular failure*.^{40, 41, 50, 52-56} Beneficial effects become evident in the first week and improvement continues during treatment. Infantile genitalia enlarge except for the testes, erections and ejaculations occur, the growth of masculine hair is stimulated, and eventually a beard may develop. Increase in virility is reflected in changes in body contour, enlargement of the larynx with a deepening of the voice, and changes in the skin and musculature. Either as a direct result of the hormone or indirectly by virtue of the encouraging changes, the emotional status improves, and there is increased confidence and aggressiveness and greater emotional stability. There is reason to mention, however, the opinion of Pullen and his co-workers⁵² that before employing substitution therapy in this condition an accurate diagnosis should be established; he even suggests that a preliminary trial of pituitary gonadotropic hormone be made. Despite favorable results with testosterone in *delayed puberty*,^{57, 58} Hamilton⁵⁹ has made the warranted suggestion that such treatment is unwise. He believes that substitution therapy can well wait a few years until it is obvious that testicular function will not begin naturally. This suggestion has merit, for testosterone stimulates only secondary sex characteristics, having no effect on the development of the testicle or of spermatozoa. In fact, in large doses it may inhibit such development. In

cryptorchidism, testosterone alone or combined with gonadotropic hormones has enjoyed some success,^{57, 58, 60} and probably deserves a trial before surgical intervention. Likewise, in *benign prostatic hypertrophy* some reports on the use of testosterone are favorable,⁶¹⁻⁶⁴ although one group⁶⁴ found no improvement in urinary symptoms. In view of the finding of decreased androgen excretion in cases with prostatic hypertrophy,^{65, 66} the use of testosterone in this condition is not irrational, and it is possible that it might be of value in early cases and poor operative risks. Further confirmation of this viewpoint appears to be needed. The use of testosterone in *male sterility* appears to us to be questionable,^{67, 68} although in one reported case of sterility associated with hypogonadism there was an increase in the number and motility of spermatozoa and two pregnancies apparently resulted from its use.⁴⁶ Most reports on the effect of testosterone in *functional impotence* are discouraging,^{46, 56, 69-71} but a favorable result has been reported with testosterone and gonadotropin combined.⁷²

Gynecologic conditions. In a wide variety of diseases peculiar to women, the male hormone has found useful clinical application. In *mastodynia* its use has met with success,^{45, 73-75} and Nathanson⁷³ has found it more effective than the estrogens. *Postpartum engorgement of the breasts* responds well to testosterone,^{74, 76-78} but dosage should be moderate (8 mg. daily by injection or 60 mg. of methyl testosterone by mouth for two days, beginning on the second to the fourth postpartum day). Abarbanel⁷⁹ finds that moderate dosage does not suppress lactation. One group⁸⁰ found testosterone of little or no value in this condition, but they employed small doses of testosterone propionate. To achieve *inhibition of lactation* some have found testosterone useful in large doses (75 mg. intramuscularly, 90 mg. of methyl testosterone orally per day).^{74, 77, 81}

Those who have used the male sex hormone in the treatment of *functional uterine bleeding* have secured very favorable results that in many cases persist after the treatment is discontinued.^{44, 45, 74, 82-85} Temporary regression in the size of *uterine fibroids* has been observed.^{30, 84, 86} Encouraging results have been reported with the use of testosterone or methyl testosterone for symptoms of the *menopause*,^{45, 74, 75} and in some individuals we have found it more effective than the estrogens. Moderate doses of testosterone given for two weeks preceding menstruation are reported to relieve *premenstrual tension*^{35, 74} and certain cases of *functional dysmenorrhea*.^{35, 45, 74, 75} Beneficial effects have been reported with the androgens in a host of other gynecologic conditions in-

cluding *afterpains*,⁷⁴ *pelvic inflammatory disease*,⁸¹ *nocturia* from various causes⁸⁸ and *nymphomania*.⁸⁹ In an experimental study of a case of *endometriosis*,⁹⁰ the symptoms were controlled by large doses of testosterone but with the production of disagreeable side effects.

General diseases. Testosterone, like most new drugs, has been tried in a variety of conditions, not always on the soundest physiologic basis. Many such trials have given surprisingly favorable results. In view of the widespread physiologic effects of testosterone, which have been discussed in an earlier part of this paper, it is perfectly possible that the male sex hormone may exert a beneficial action on systems other than the urogenital tract.

Testosterone, alone or combined with gonadotropins, has been used and is recommended in cases of *retarded growth*,^{46, 91-93} where it produces marked increases in growth rate and bone development.^{19, 91, 94} Conversely, it has been reported to be useful in arresting *abnormally rapid growth*.^{92, 95} In our experience with a large number of adolescents with retarded growth the effect of prolonged use of methyl testosterone has been striking, indeed far better than that achieved with any other therapy. Although the response is more marked in the first six months of therapy, there continues to be a satisfactory growth for many months thereafter. To achieve these effects, however, it is essential that the bone epiphyses be open. It is not surprising, perhaps, that better results are obtained in children who have not an inheritance of small stature.

In a host of psychoses, testosterone compounds have been used with varying degrees of success. Cases of *agitated depression*⁹⁶ and *atypical involutional psychoses*⁹⁷ have responded encouragingly to testosterone. Both good and poor results have been obtained with testosterone in *male involutional psychoses*.^{98, 99} One patient with *schizophrenia associated with hypogonadism* made a striking recovery with androgens,¹⁰⁰ but the physical abnormalities may have had a major share in the patient's mental derangement. In the same manner, *behavior problems in adolescence* when associated with hypogonadal states tend to disappear after the physical inferiority has been improved with testosterone.⁵⁸ Because of the frequent remissions and relapses that may occur spontaneously in most psychoses, one must await better controlled studies, larger series of cases and longer periods of observation before venturing to appraise this aspect of testosterone therapy.

Various *dermatitides associated with senescence* in males have responded to androgen therapy after other treatment had failed.¹⁰¹ An interesting ap-

plication of testosterone is its recent use in certain disorders of the vascular system. In *essential hypertension* and *peripheral vascular disease*¹⁰² sufficient improvement has been reported to warrant further investigation.¹⁰² Lesser,¹⁰³ Bonnell and others,¹⁰⁴ Hamm¹⁰⁵ and Walker¹⁰² all report good results in the treatment of *angina pectoris* with testosterone, although such treatment did not prevent the occurrence of a coronary occlusion in one patient.¹⁰²

Two patients with *myotonia atrophica*, associated with testicular atrophy, responded markedly to testosterone treatment, whereas a patient with no testicular involvement did not improve.¹⁰⁶

Possible Harmful Effects

The conscientious physician before employing a new drug wants to be informed of the deleterious effects that may attend its use. Permanent harm resulting from the moderate use of testosterone remains to be demonstrated. It must be remembered, however, that the synthetic androgens are comparatively new and have had only a limited clinical trial.

Some have warned against the use of testosterone in growing persons on the ground that it may cause premature epiphyseal union and consequent dwarfing.¹⁰⁷ Pullen and his group⁵² found no advance in bone age in children who received 30 mg. of testosterone propionate weekly, although when 75 mg. was administered per week such changes did occur. Others in fairly large series found no evidence of epiphyseal closure or advance in bone age.^{57, 91, 94}

Moore¹⁰⁸ has stated that the administration of androgens to males with normal testicles may be harmful; and indeed, decreases in number of spermatozoa and in ejaculation volume have been noted.^{50, 107, 109} Such observations emphasize the need for a definite diagnosis of diminished testicular function before employing substitution therapy in the form of testosterone and condemn its indiscriminate use in normal man. Eidelsberg and Ornstein¹¹⁰ have shown that in eunuchoid males testosterone treatment may be employed over long periods of time without ill effect. Gynecomastia has occasionally been observed in males during testosterone therapy,^{50, 59} but in our experience this effect is only transient and disappears with reduction or elimination of the drug.

In females receiving androgenic therapy, the commonest untoward effects are the appearance of hirsutism, deepening of the voice and hypertrophy of the clitoris,^{45, 67, 75, 83, 84, 80, 90, 111} The change in voice remains, though these other effects are transient and regress if treatment is immediately stopped. It is occasionally noted that the increased hirsutism remains after discontinuing the drug,

but this is not easy to evaluate. Moreover, with dosage below 250 mg. of testosterone propionate per month, such effects are extremely unlikely.⁸² Acne,⁸⁴ weight gain⁸⁴ and increased libido⁴⁵ are occasional and transitory side effects in women. Increased libido may be marked in castrated women. Wollner¹¹² has reported a proliferative change in the cervical mucosa resembling carcinoma in a patient with chronic cervicitis who received fairly large doses of testosterone propionate.

Dosage

With so many effective routes of administration available to the physician, each with its advantages and drawbacks, it is difficult to recommend one above another. Dosage and form of administration will vary depending on the economic status of the patient, age and sex, and the condition that is being treated. A standard treatment regimen may, however, be suggested, to be changed in accordance with individual factors. It might consist of intramuscular injection of testosterone propionate in doses of 20 to 25 mg. three times weekly until the desired effects are produced, then substitution of maintenance doses of 10 to 40 mg. daily of methyl testosterone by mouth. Children should not receive more than half the adult dose, and in the case of women it is well to keep below a total of 300 mg. per month in order to avoid the masculinizing effects that are good evidence for reducing the amount of the drug. Where different dosage has been suggested for specific conditions, we have endeavored to include it in the discussion.

SUMMARY

Testosterone is a synthetic and as yet fairly expensive product identical with a testicular hormone. Its most dramatic therapeutic effects are seen when it is used in the form of physiologic replacement therapy in true testicular failure, but it has been shown to have beneficial effects in other diseases. Its evaluation in many of these conditions must await further investigation. There is as yet no evidence of permanent harm resulting from its moderate and clearly indicated usage.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Stated Meeting, February 3, 1943

A STATED meeting of the Council of the Massachusetts Medical Society was called to order by the president, Dr. George Leonard Schadt, at 10.30 a m, on Wednesday, February 3, 1943, in John Ware Hall, 8 Fenway, Boston; 175 councilors (Appendix No 1) were present

The Secretary offered the record of the meeting held October 7, 1942, as published in the *New England Journal of Medicine*, issue of November 12, 1942, and moved its adoption. This motion was seconded by Dr. Peirce H. Leavitt, Plymouth, and it was so ordered by vote of the Council.

The report of the Auditing Committee for the year ending December 31, 1941 (Appendix No. 2) was presented by Dr. LeRoy A. Schall, West Newton, chairman. Dr. Schall explained that this report was not offered in February, 1942, because the accountant's report had not been received sufficiently early to make this possible.

He spoke of having approached the Treasurer with a view of learning what the duties of the Auditing Committee were. He quoted the latter as having said that it was not necessary for the Auditing Committee to appear before the Council. A statement signed by the committee and addressed to the Council, to the effect that the latter had examined the accountant's report, was all that was necessary. Dr. Schall moved the adoption of the report. This motion was seconded by a councilor, and it was so ordered by vote of the Council.

The report of the Auditing Committee for the year ending December 31, 1942 (Appendix No. 3), was presented by Dr. Burton E. Hamilton, Brookline, in the absence of Dr. Francis C. Hall, Brookline, chairman.

The report spoke of the duty of the Auditing Committee to require the examination by a certified public accountant of the assets and liabilities of the Society as represented by the Treasurer's books and accounts, and said that this duty had been fulfilled. The report continued to say that the members of the committee had talked with the Treasurer *pro tempore* and had been assured by him that the examination had been thoroughly made and that to this extent the accountant's examination had been "verified" by the committee. The report added that if this represents the total obligations of the Auditing Committee, its work has been done. If, on the other hand, it is the duty of the Auditing Committee to afford assurance to the Council that the finances of the Society are adequately protected, the committee has not fulfilled its obligations, although it has been given assurance that auditing committees in the past have confined their efforts to what the present committee has done.

There were four specific recommendations contained in the report: first, that the investment of the Society's funds should be under the direction of a professional investment company; second, that the report of the accountant should be more com-

plete and include a list of investment transactions; third, that the latter should include a statement that the report of the fiscal year is reconciled with the report of the preceding year, and fourth, that the duties of the Auditing Committee be turned over to a business man trained as a bank examiner.

It was moved by Dr. Hamilton that the report be accepted. This motion was seconded by a councilor and it was so ordered by a vote of the Council.

It was moved by Dr. Francis P. Denny, Norfolk, that the recommendations contained in the report be referred to the Executive Committee. The motion was seconded by a councilor and it was so ordered by vote of the Council.

The Treasurer's report (Appendix No. 4) was offered by Dr. Eliot Hubbard, Jr., treasurer *pro tempore*. This report contained the following interesting information: the revenue of the Society from resident dues in 1942 was \$49,182.39 as compared with \$49,779.00 in 1941 and \$1738.25 from nonresident dues as compared with \$1670.75 in 1941. The total revenue from dues in 1942 was \$50,920.64.

Other revenue to the Society was \$3932.12 from invested funds (not including the Building Fund); \$17.30 from sales; \$288.65 from profits from the sales of securities; \$3287.75 from the sales of booths at the Annual Meeting; \$139.80 from subscriptions to the *Journal* from fellows in the service and \$558.00 from censors' examinations. This represents a total revenue of \$59,144.26, an increase of \$1444.96 over 1941. The income from the Building Fund was \$1844.19 plus \$72.66, the latter representing a profit from the sale of securities. The total Building Fund now stands at \$63,991.80. In 1942 the Society's total expenses were \$48,680.84. The unexpended revenue for the same year was \$10,463.42. This compares with a total expense in 1941 of \$45,310.47 and unexpended revenue that year of \$12,388.83. The Society ended the year of 1942 with total assets, cash and securities, of \$229,951.27 plus unexpended revenue of \$10,463.42.

There was much discussion at this point concerning the proper form in which reports offered to the Council should be handled by the Council. Should such reports be received, accepted or adopted? The President requested Dr. Frank R. Ober, Suffolk, to engage in research to this end. This the latter did. He read from *Robert's Rules of Order* to the effect that, although these terms are often used indiscriminately, the term "adopt" is preferable and least likely to be misunderstood.

Dr. Lester M. Felton, Worcester, moved that the Treasurer's report be accepted. This motion was seconded by a councilor and it was so ordered by vote of the Council.

REPORT OF EXECUTIVE COMMITTEE

This report (Appendix No. 5) was presented by the Secretary. The report spoke of two meetings which the committee held, one on October 21, 1942, and the other on December 30, 1942. The meeting held in October was of an emergency character and was called for the purpose of giving consideration to a vote adopted by the Massachusetts Board of Registration in Medicine, to wit:

Voted to ask the Governor of Massachusetts to waive the law (Chapter 112, Section 2, T. E.) to the effect that we may temporarily permit members of the medical profession, who are graduates of approved schools, who are registered to practice in other states and who are recommended by the National Procurement and Assignment Service, to practice in Massachusetts during the emergency without payment of the registration fee, and without examination.

The purpose of this action on the part of the Board was to facilitate the work of the Procurement and Assignment Service in relocating physicians during the present emergency and it was undertaken as a result of a conference between the Board, Dr. Lahey, Dr. Fitz and certain officers of the Massachusetts Medical Society. The report continued to say that Governor Saltonstall was willing to use his wartime emergency powers in this direction provided the Massachusetts Medical Society approved and that the Executive Committee, in the name of the Massachusetts Medical Society, gave its unanimous approval.

The Secretary moved that the Council approve this act of the Executive Committee. This motion was seconded by a councilor and it was so ordered by a vote of the Council.

The report spoke of the subsequent fate of this matter. The Attorney General, when approached for the purpose of actually drawing up the act, advised against it, because he was not convinced of its need in Massachusetts at that time. He made it clear, however, that he was without prejudice against the time when this need might arise in this state. He also spoke of the possibility of legislative action along this line. The report added that the committee had given consideration to this latter course of action, since such action had been urged by the Executive Committee of the Federation of State Medical Boards and recommends adversely on this particular proposition, because a directive from the Governor, when and if such a need develops, is much the simpler approach.

The Secretary moved the adoption of the recommendation. This motion was seconded by a councilor and it was so ordered by a vote of the Council.

The Executive Committee, acting on the recommendations of the Committee on Membership,

retired eleven fellows, restored eight to membership and accepted the resignations of four.

The committee approved of the recommendations contained in the reports of the Committees on Membership, Finance, Public Relations and Arrangements.

The committee commended to the Council the report of the Committee on Medical Education anent the nursing situation.

The committee recommended that the question of establishing a junior membership in the Massachusetts Medical Society, raised in a letter from Dr. Reginald Fitz, be referred to the Committee on Membership.

The Secretary moved the adoption of this recommendation. This motion was seconded by a councilor.

Dr. I. R. Jankelson, Norfolk, asked for a definition of junior membership. The Secretary suggested that Dr. Fitz might more properly answer this question. In reply, Dr. Fitz said that the matter will come up later in a report that he would submit. Dr. Jankelson thought that no action should be taken on this matter until more was known about it. The recommendation was adopted by vote of the Council.

The committee recommended the creation of a war-participation committee of five to be appointed by the President to act in conjunction with a similar committee of the American Medical Association. The Secretary moved the adoption of the recommendation. This motion was seconded by a councilor. Dr. Ernest L. Hunt, Worcester, asked what the duties of such a committee would be. The Secretary suggested to the President that Dr. Roger I. Lee, Suffolk, president-elect of the Massachusetts Medical Society and chairman of the Board of Trustees of the American Medical Association be permitted to answer Dr. Hunt's question.

Dr. Lee said that a war participation committee would take the place of the old Committee on War Preparedness, the functions of which latter committee have largely been taken over by a governmental agency, the Procurement and Assignment Service, which is responsible to the government and not in any way to medical societies. Dr. Lee added that it seemed desirable to have committees appointed by medical societies and responsible to them which could act as a sort of clearing house and liaison between the medical societies and Procurement and Assignment Service in the work that this latter agency is called on to do.

Dr. Hunt asked how such a committee could do anything without an appropriation. Dr. Lee replied that such a committee might need a modest appropriation. There was much discussion on the

matter, participated in by Dr. Robert N. Nye, Suffolk, Dr. Fitz and Dr. Carl Bearse, Norfolk.

The recommendation was adopted by vote of the Council.

The committee recommended that the request of Dr. Charles S. Butler, treasurer, for an indefinite leave of absence because of illness be granted, and that the Council express its very great thanks for his fine service to the Society and its regret that he had found such a step necessary. The Secretary moved the adoption of this recommendation. This motion was seconded by a councilor and it was so ordered by vote of the Council. The committee approved of the recommendation of the Committee on Finance that Dr. Butler's salary be paid to him up to and including December 31, 1942.

The Secretary acknowledged the receipt by the President of a letter dated January 28, 1943, in which Dr. Butler resigned as treasurer of the Massachusetts Medical Society. On a motion by the Secretary and a second by a councilor, this communication was laid on the table.

The committee acknowledged the receipt by the President of the following letter from Dr. William J. Brickley, Suffolk:

December 30, 1942

Dr. George Leonard Schadt, President
Massachusetts Medical Society
Boston, Massachusetts

Re: Gift to Massachusetts Medical Society

Dear Doctor:

Enclosed please find my check for \$1000 as a gift to the Massachusetts Medical Society, to be used in carrying out its usual functions as an educational body.

I would suggest that—though I do not make it a binding condition of the gift—this fund be used to procure any necessary lunches for the official meetings of the Committee on Ethics and Discipline. I have in mind the many hours spent and the difficult problems dealt with, not hastily, at such meetings.

Please advise me whether the Society will accept this gift.

Sincerely,

WILLIAM J. BRICKLEY, M.D.

The committee offered three recommendations with regard to this gift: that it be accepted by the Council with thanks; that it be used to create a fund which shall be known as the Dr. William J. Brickley Fund; and that it be used for the purpose outlined in Dr. Brickley's letter until otherwise ordered by the Council.

The Secretary moved the adoption of these recommendations. This motion was seconded by a councilor and it was so ordered by vote of the Council.

The committee had reviewed a list of appointments made by the President and had given them its approval.

The Secretary moved the adoption of the report of the Executive Committee as a whole. This motion was seconded by a councilor and it was so ordered by vote of the Council.

REPORTS OF COMMITTEES

Committee on Arrangements—Dr. Gordon M. Morrison, Middlesex South, chairman

The report, which was offered by Dr. Roy J. Heffernan, Norfolk, reads as follows:

I beg to submit herewith the report of the Committee on Arrangements. Owing to the present unsettled conditions surrounding us, the committee has three recommendations to make, all of which have been reviewed and approved by the Executive Committee: that the Council rescind its action of May, 1942, naming Springfield as the place of the annual meeting in 1943; that Boston be the place of the meeting in 1943; and that following the passage of the present emergency, the Council give serious consideration to Springfield as a suitable place for an annual meeting.

Dr. Heffernan moved the adoption of these recommendations. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Dr. Heffernan then made the following announcement:

Owing to the fact that the committee could not secure the proper hotel accommodations in Boston for May 17, 18 and 19, the Committee on Arrangements has changed the dates of the annual meeting. These new dates are May 24, 25 and 26.

The report as a whole was adopted by vote of the Council following a motion by Dr. Heffernan and a second by a councilor.

At this point it was explained to Dr. William A. R. Chapin, Hampden, that Dr. Spaid had sought retirement.

Committee on Publications—Dr. Richard M. Smith, Suffolk, chairman

This report (Appendix No. 6) said that Dr. George W. Thorn, Hersey Professor of the Theory and Practice of Physic at Harvard University and physician-in-chief at the Peter Bent Brigham Hospital, would deliver the Shattuck Lecture at the annual meeting.

It quoted Dr. Nye's report to the committee:

During 1942, the *New England Journal of Medicine* received 1984 new "outside" subscriptions, a total that is over 50 per cent greater than the total received in 1941. Of these subscriptions, 1085 were from regular subscribers and 899 from medical students. As would be expected, there were many cancellations, undoubtedly owing to enlistment in the armed forces; the net increases were 216 regular subscribers and 711 medical students, which total 927. As of December 31, 1942, journals were being sent to 5083 members of the

Society (a decrease of 74 from the 1941 figure), 3462 regular subscribers and 1193 medical students, a total of 9738, which is greater by 853 than the total for 1941. This does not include 348 members of the New Hampshire Medical Society, who receive the *Journal* once a month.

The editorial board took action on 238 manuscripts during 1942, a decrease of 90 compared with the figure for 1941. Of these papers, 169, or 71 per cent, were accepted.

There was a net loss of \$17,550 in operating the *Journal* in 1942. This represents \$3.43 per member of the Society and is approximately \$2450 less than the amount appropriated by the Society. The net cost per member was \$3.20 in 1941. A larger circulation, increased costs in binding and mailing, and fifty-three issues in 1942, a situation which arises every seven years, represent the reason for increased operating expenses in 1942.

It was stated that the operating expenses would probably be lower in 1943. This was predicated on a smaller total circulation and higher advertising rates, the latter being effective January 1, 1943. If it became a choice between cutting the pagination of the *Journal* or the acceptance of papers for publication below the *Journal's* present standards, the pagination would suffer the cut.

Dr. Smith moved the adoption of the report. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Committee on Membership—Dr. Harlan F. Newton, Suffolk, chairman

This report (Appendix No. 7) recommended adversely on the petition of Dr. Morris A. Cohen, 452 Beacon Street, Boston, for reinstatement to membership in the Massachusetts Medical Society.

Dr. Newton moved the adoption of this recommendation. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Dr. Walter Fenno Dearborn, 79 Fresh Pond Parkway, Cambridge, because of eminent work in the allied sciences, was recommended for associate fellowship in the Massachusetts Medical Society.

Dr. Newton moved the adoption of this recommendation. This motion was seconded by a councilor and it was so ordered by vote of the Council.

The committee offered the following recommendations:

1. That the following recommendation from the then Committee on Membership, passed by the Council February 5, 1941, be revoked: "Fellows of the Society who are called to full-time service in the United States Army, Navy or Public Health Service during the present emergency and whose livelihood is thereby impaired may, on written application to the Treasurer stating their situation, have their dues remitted for the year of service. A period of full-time service greater than six months shall give the privilege of a year's

remission of dues. The *New England Journal of Medicine* will be sent to such members only on payment of an annual fee of four dollars (\$4.00). The president of the Society shall determine the end of the present emergency."

2. That the following recommendation be passed: "Fellows of the Massachusetts Medical Society who have enlisted or been called to full-time service in the United States armed forces or in the United States Public Health Service during this present war shall have no further dues collected for the duration, their names continued on the membership roll of the Society as active members in good standing, and to only such members as request it will the *New England Journal of Medicine* be sent and then only on payment of an annual subscription fee of \$4.00 per year. Any members who have joined or who subsequently join the United States armed forces or the United States Public Health Service should advise personally or by some other means the Treasurer of the Society to facilitate omission of dues. 'For the duration' is interpreted as meaning honorable discharge from the United States armed forces or United States Public Health Service."

3. That a flyer of this recommendation be attached to every bill or communication relating to indebtedness sent from the Treasurer's office of the Massachusetts Medical Society to its members.

Dr. Newton moved the adoption of recommendation No. 1. This motion was seconded by a councilor.

Dr. James P. O'Hare, Suffolk, asked if this recommendation included withdrawal from the Council or from committees. He added that some men have the idea that they should drop their positions as councilors and others that they should not, and that this same holds true with regard to membership on some of the committees of the Suffolk District Medical Society. Dr. Newton replied that he thought it would apply to any councilor in any capacity. In reply to further questioning by Dr. O'Hare, Dr. Newton said that it was his view that the councilors referred to would lose their positions automatically. Dr. Schadt expressed a like view. Dr. O'Hare added that at least one such councilor had asked that he be retained in the Council.

Dr. Chapin asked what provision is made for the men who will continue in the service after the present emergency is over. He added that they might be carried for the rest of their lives, absolved of paying dues. Dr. Newton replied that he thought that was a matter which could be taken up at the end of the year.

Dr. John Homans, Suffolk, asked if the adoption of this recommendation will cause the Treasurer to refuse tender of dues on the part of those in the armed forces. Dr. Schadt at this point said that it was evident that much more thought and study should be given to this matter and suggested that it might be wise to refer the whole matter to the Executive Committee.

Dr. G. Colket Caner, Suffolk, said that he had worded the previous rules, after conversations with Dr. Butler. He said that it was their joint viewpoint that members who had entered the armed forces and who wished to continue to pay their dues should be permitted to do so. He said he approved of the leaflets which it was suggested should be added to the bills sent out by the Treasurer. He thought, however, that the old way of having the individual fellow decide for himself whether he should or should not request that his dues be remitted had many advantages. Dr. Newton replied that it was not the intent of the Committee on Membership to say to these fellows that they cannot pay their dues if they so desire.

Dr. Nye asked if the recommendation read that the Treasurer "shall not accept." Dr. Newton answered, "No." Dr. Nye asked for a reading of the first of recommendation No. 2. Dr. Newton read as follows:

Fellows of the Massachusetts Medical Society who have enlisted or been called to full-time service in the United States armed forces or in the United States Public Health Service during this present war shall have no further dues collected for the duration.

Dr. Nye asked if that did not mean that the Treasurer shall not accept dues even though they are sent in. Dr. Newton replied that it might be interpreted that way.

Dr. Walter G. Phippen, Essex South, asked if the former method was working any hardship on anybody. Dr. Newton replied in substance that this was partly so.

Dr. Donald Munro, Suffolk, suggested that the Council rescind the action of the Council as of February 5, 1941—recommendation No. 1—and refer the other recommendations to the Executive Committee. Dr. Nye pointed out that if this course were followed, the Society would have no means of remitting dues until such time as the Executive Committee had had time to act.

Dr. Caner thought that the whole matter might be covered quite well if a flyer were attached to each bill sent out by the Treasurer, calling each fellow's attention to the fact that, if they had entered the armed forces, they might have their dues remitted if they so desired and that these same men might continue to receive the *Journal* by the payment of \$4.00.

Dr. Elmer S. Bagnall, Essex North, thought this matter should be referred to the Executive Committee as a means of saving the Council's time.

Dr. Newton, with permission of the Council, withdrew his original motion as did the seconder. He then moved that the matter be recommended, for investigation and action, to the Executive Com-

mittee. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Committee on Finance—Dr. John Homans, Suffolk, chairman

The report was published in the *New England Journal of Medicine*, issue of January 14, 1943.

Dr. Homans, in offering this report, spoke of the difficulty in these times of actually forecasting the income of the Society. His committee thought that \$50.00 was a fair allowance for the expenses of a committee that was statewide in its composition.

He called attention to the expense of the Secretary's office which was more or less itemized. He said that the Secretary's office assumed many expenses of other committees and it was difficult to know where to assign these expenses. This was, however, he added, merely a matter of bookkeeping. He said that the same was true, to some extent, of the Treasurer's office. He pointed out that, now the bills for dues go directly to the members from this office, an item for the expense involved is included in the budget for that purpose. He said it might be necessary to employ a bookkeeper and that \$1000 was set down to cover this contingency.

He spoke of the rather large item in the budget to cover the maintenance of the Society's headquarters. He said that this was a rather complicated item and had to do with dealings between the Society, the *Journal* and the Boston Medical Library. He said that the *Journal* hires the various bookkeepers, clerks and so forth, and that the Society pays the *Journal* for their services to the extent that it uses them. Rent is paid not directly to the Boston Medical Library but through the *Journal*. Dr. Homans said that his committee has suggested to Dr. Robey that he and the Treasurer get together and produce something that all can understand. He spoke of the \$500 which was put down as a probable expense of holding the annual meeting and that it now was quite likely that this money would not be needed. He spoke of the reduction by \$5000 in the amount set down against the needs of the *Journal*.

Dr. Carl Bearse called attention to the by-law which requires that any expenditure of \$100 or more shall be broken down when so requested by a fellow. With this as a preamble, he requested that two large items, one for \$42,000, representing the publication cost of the *Journal*, and the other \$22,000 representing office and other salaries be broken down.

Dr. Homans broke down the second item as follows:

Editor	\$7,000
Associate editor	360
Associate editor	360
Assistant editor	3,000
Editor's assistant	1,380
Office secretaries	1,872
	1,664
	1,300

With regard to the first item he read the following figures:

Printing	\$17,000
Stock	10,000
Binding and mailing	12,000
Engraving	3,000
Total	\$42,000

Dr. J. Harper Blaisdell, Middlesex East, made the following motion: First, under paragraph "Expenses of Officers and Delegates," that the item "Society Headquarters (general expenses) \$4500" be stricken out and, second, that under the paragraph "Standing Committees," that the sum of \$4500 be substituted for the zero after "Society Headquarters." Dr. Homans said he had no objection to this change. Dr. Fitz seconded the motion and it was so ordered by vote of the Council.

Dr. Channing Frothingham, Suffolk, moved that the report of the Committee on Finance be accepted. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Dr. Homans moved the adoption of the budget subject to the change indicated by Dr. Blaisdell's motion. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Committee on Ethics and Discipline—Dr. Ralph R. Stratton, Middlesex East, chairman

Dr. Stratton reported as follows:

Mr. President, the Committee on Ethics and Discipline has no stated report to make today. Either owing to the improved ethical morale of the members or to the fact that we have lost some of our troublesome problems, we have had very few complaints this last year.

On a motion by Dr. Stratton and a second by a councilor, this report was accepted by vote of the Council.

Committee on Medical Education—Dr. Robert T. Monroe, Norfolk, chairman

The complete report of this committee appeared in the *New England Journal of Medicine*, issue of January 14, 1943.

Dr. Monroe spoke as follows:

Our studies on the nursing situation created by the war have been printed in the January 14, 1943, issue of the *New England Journal of Medicine*. Our conclusions from these studies are that there is a shortage of nurses in this state and in the country, and that it is real, present and serious. This shortage of nurses does not appear to have come about as a result of shortsightedness on the part of responsible individuals. On the contrary, we have been impressed with the efforts of federal authorities and of hospital, civilian-defense and nursing executives to avert the shortage early and late. As we see it, the chief difficulty has been to get the workers—nurses for war work, pupils for graduate-nurse and attendant-nurse schools and women for ward helpers and Red Cross volunteer nurse's aides.

We believe that the needs of the armed forces can and will be met. The civilian-defense situation is fairly well in hand, for it is well organized and has a growing reserve of paid and volunteer workers; but there is no evidence that the reserve is large enough to meet an epidemic situation in the next few months. We are in doubt concerning the ability of hospitals to continue adequate nursing service for their patients for the duration of the war in times, such as the present, which are not obviously emergencies and therefore do not provoke the maximum efforts of all concerned. Hospitals are experimenting with various solutions and are getting the loyal co-operation of nurses and volunteers, but their position is far from secure.

Federal authorities have these matters under consideration and are in the process of deciding upon one or more solutions. We have heard of the plans and must confess that none seem ideal. However, one supplementary step might be taken at once, and that is to establish training schools in the large Army and Navy Hospitals. Teaching staffs could be assembled from the Army and Navy Nurses Corps and from civilian schools. Such schools could train easily several thousand pupils who in six months' time could become useful to those hospitals. Meanwhile it would appear to be the duty of every physician to foster in every possible way the growth and effectiveness of the graduate-nurse and attendant-nurse schools and the Red Cross volunteer-aide classes.

On a motion by Dr. Monroe and a second by a councilor the report was adopted by vote of the Council.

Committee on Public Health—Dr. Francis P. Denny, Norfolk, chairman

No report.

Committee on Medical Defense—Dr. Arthur W. Allen, Suffolk, chairman

No report.

Committee on Society Headquarters—Dr. William H. Robey, Suffolk, chairman

No report (see report of Committee to Aid the Boston Medical Library).

Committee on Industrial Health—Dr. Dwight O'Hara, Middlesex South, chairman

Dr. O'Hara spoke as follows:

On November 7 the Committee on Industrial Health held a morning, afternoon and evening program at the Harvard Club of Boston. Three hundred and eighteen persons, exclusive of speakers and committee members, registered, and when questioned responded to the effect that the meeting was not only worth while but worth repeating with another program. The committee is therefore arranging for a similar meeting, also to be held on a Saturday and at the Harvard Club, probably in April. The details of this meeting will be announced in the *New England Journal of Medicine*.

The committee has now had on file for some months the names and pertinent data concerning three hundred or more Massachusetts physicians who have signified their interest in and their availability for industrial medical practice. These data are also compiled on a punch-card system at the office of the Division of Occupational Hygiene of the State Department of Labor and Industries, and its availability was brought to the attention of the Associated Industries of Massachusetts at their annual meeting last fall. The fact that there have been only three or four inquiries from industrial plants seeking medical service, after what would seem to have been adequate publicity concerning this list, indicates that in Massachusetts at least the supply of industrial medical service is ample, and still is in excess of its demand.

Dr. O'Hara moved the adoption of the report. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Massachusetts Committee on Procurement and Assignment—Dr. Reginald Fitz, chairman

The report (Appendix No. 8), by courtesy of the committee, was presented by Dr. Fitz, who moved its adoption. This motion was seconded by a councilor and it was so ordered by vote of the Council.

The Council adjourned for luncheon at 1:00 p.m. and reassembled at 1:50 p.m.

Committee on Public Relations—Dr. Elmer S. Bagnall, Essex North, secretary

Dr. Bagnall reported as follows:

The committee held one meeting, on December 16, 1942, with members of the subcommittee on workmen's compensation hospitalized cases (Drs. Ellison, Gordon, Morrison and Scannell). The report of this subcommittee was considered and adopted and is recommended to you for adoption.

After conference with the Industrial Accident Board's advisory committee there was agreement with the Ellison subcommittee on the following:

(1) Freedom of choice in hospitalized cases should hereafter be defined as the selection by the injured (or his agent) of a physician from two lists, one containing the names of all physicians eligible to practice in the hospital concerned and the other the names of physicians submitted to the hospital by the insurer.

(2) The Ellison subcommittee was authorized to offer its support to the committee now revising the Industrial Accident Board's fee schedule.

The President invited the committee's attention to recent editorials and letters in the *Boston Herald* relating to our alleged attitude toward refugee physicians. The committee believes that organized medicine is misrepresented often enough to make it desirable that a subcommittee, not limited to the personnel of the Committee on Public Relations, be appointed to look into this matter and report to the Committee on Public Relations. If the committee finds ground for action you will then be asked whether you want a professional publicity agent to interpret fairly the attitude of the Society as the occasion arises.

Dr. Bagnall moved that the report be accepted and the recommendations adopted. The motion was seconded by a councilor and it was so ordered by vote of the Council.

Committee on Tax-Supported Medical Care — Dr. Bagnall, chairman

This report was as follows:

The committee, through the chairman, is working in liaison with the Department of Public Welfare at the State House. There have been no matters of policy change necessitating a meeting of the entire committee. It seems desirable to continue the life of this committee despite the lull in current activities, so this is submitted as a report of progress.

Dr. Bagnall moved that the report be adopted as a report of progress. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Committee on Postpayment Medical Care (Bank Plan) — Dr. Bagnall, chairman

This report was as follows:

We are still awaiting the call of the committee from the Massachusetts Bankers Association who now hold the initiative.

Dr. Bagnall moved the adoption of this report. The motion was seconded and it was so ordered by vote of the Council.

Committee to Meet With the Medical Advisory Committee of the Industrial Accident Board — Dr. Daniel J. Ellison, Middlesex North, chairman

No response.

Committee on Prepayment Medical-Care Costs Insurance — Dr. James C. McCann, chairman

This report (Appendix No. 10) was presented by Dr. McCann, who moved its adoption. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Committee on Legislation — Dr. Brainard F. Conley, Middlesex South, chairman

Dr. Conley reported as follows:

This committee is now composed of eighteen members, one from each district of the Society, elected by ballot at the annual meeting of each district. The personnel of the committee at its start was as follows: Berkshire, P. J. Sullivan; Franklin, H. G. Stetson; Hampshire, J. D. Collins; Hampden, W. A. R. Chapin; Worcester North, H. D. Bone; Worcester, L. M. Felton; Essex North, E. H. Ganley; Essex South, C. A. Worthen; Middlesex North, W. H. Sherman; Middlesex East, K. L. MacLachlan; Middlesex South, B. F. Conley; Suffolk, W. B. Breed; Norfolk, D. L. Lionberger; Norfolk South, J. E. Knowlton; Plymouth, C. D. McCann; Bristol North, J. L. Murphy; Bristol South, E. H. Cody; Barnstable, not elected. There have been two resignations. D. L. Lionberger, of Norfolk, was the first to enlist in the service of his country and he has been succeeded by J. V. Fisher of their district. Shortly afterward, K. L. MacLachlan, of Middlesex East, enlisted and he has been succeeded by J. M. Wilcox. Both these men have done noble service for this society and they are now doing noble work for their country. This committee is proud of both of them. On October 21, 1942, on a call from the President, this committee met and organized. Brainard F. Conley, of Middlesex South, was elected chairman and Lester M. Felton, of Worcester, was elected secretary. It was voted that a committee of five members be appointed by the chairman, to consist of the chairman and four others, to act as a working committee, with authority to act for the full committee and that they be empowered to use their discretion in an emergency. The chairman has appointed the following four members: L. M. Felton, W. B. Breed, J. V. Fisher and C. D. McCann. This committee of five has already started going over the legislative petitions.

Because of so many members of the Society already in the armed forces of our country and more to go, we realize that the income of the Society will for this year be considerably lessened. For this reason we voted to discontinue the "Legislative Bulletin" for the duration.

The committee wishes to extend its thanks to the editor of the *New England Journal of Medicine* for his immediate willingness to publish, as often as necessary, such legislative matters as will be of interest to the members of the Society. We believe that this will have certain advantages over the bulletin, in that you will have knowledge of pending legislation much more promptly than heretofore. We therefore suggest that you watch each issue of the *Journal* from now on until the end of the present legislative year for your legislative information. After all, the *Journal* is the official organ of the Society.

Up to January 27, there have been twenty-eight petitions in the House of Representatives and four in the Senate which, in the opinion of the Legislative Reporting Service, are of concern to medicine. All these seem to be of more or less interest and are in the process of study as to their importance. So far there does not seem to be any incidence of new legislation. Some of the year-after-year bills are missing, at least up to now. For example, there is no "annual registration" petition, and the osteopaths and chiropractors are apparently occupied with things other than legislation.

We have published in the current issue of the *Journal* the whole of a petition which calls for the repeal of the provisions of the law requiring premarital serologic tests. This bill is marked for a hearing on March 11. We are inclined to believe we should lend our aid in retaining the blood test part of the present law.

There is another blood test bill which has come to our attention. It is numbered House 869 and reads as follows:

Every qualified physician shall, not less often than once in every period of six months submit to and take a blood test for the social diseases syphilis and gonorrhea, under rules and regulations promulgated therefor by the board of registration in medicine and shall at all times have permanently displayed in each of his offices or places of business a certificate of the board stating the date and the results of each last blood test.

We hope to have completed the study of all bills within the next two weeks and as soon as possible our recommendations as to action on each will be published, as well as the dates of hearings.

We have no recommendations to make at the present time.

Dr Conley moved the adoption of this report. The motion was seconded by a councilor and it was so ordered by vote of the Council.

Dr Conley called attention to the *Journal of the American Medical Association*, issue of January 23 1943, page 267, and advised all to read this material which represents the opinion of the court in affirming the guilt of the American Medical Association.

Committee on Cancer—Dr Shields Warren, Suffolk, chairman

No report

Committee on Postgraduate Instruction—Dr Reginald Fitz, Suffolk, chairman

No report

Military Postgraduate Committee—Dr W Richard Ohler, Jamaica Plain, chairman

No report

Committee on Physical Therapy—Dr Franklin P Lowry, Middlesex South, chairman

No report

Committee on Expert Testimony—Dr Frank R Ober, Suffolk, chairman

No report

Committee on Automobile Insurance Claims—Dr Henry C Marble, Newton Centre, chairman

No report

Committee on Convalescent Care—Dr T Duckett Jones, Roxbury, chairman

No response

Committee to Study the Practice of Medicine by Unregistered Persons—Dr Richard Dutton, Middlesex East, chairman

No report

Committee to Meet with Massachusetts Hospital Association—Dr Walter G Phippen, Essex South, chairman

No report

Committee to Examine WPA Records—Dr Guy L Richardson, Essex North, chairman

No report

Committee on Maternal Welfare—Dr Judson A Smith, Newton Centre, chairman

No report

Committee on Rehabilitation—Dr William E Browne, Suffolk, chairman

Dr Browne reported as follows:

There has been no occasion for this committee to meet since the last meeting of the Council and no meeting has been held. A few days ago a communication was received from the Subdivision on Health of the Massachusetts Committee on Public Safety. That communication states that a program is to be worked out whereby the Industrial Rehabilitation Division of the State Department of Education, through local rehabilitation agents now appointed, will determine which of those classified IV F in the draft may be returned to various war industries.

The plan anticipates that lay persons who have had some training as a nurse or social worker will review the confidential records indicating the cause for rejection of certain draftees. No action by the Council seems necessary on this matter at present. An expression of opinion would be appreciated from the Council concerning the desirability, if possible, of registered physicians in the Commonwealth reviewing these confidential matters with the hope of being of assistance to rehabilitation agents and others interested in returning a considerable number of men to various war industries. And so I have to report that that has just come to our attention.

Dr Browne moved the adoption of the report, this was seconded by a councilor and it was so ordered by a vote of the Council. He then moved that the Council recommend that these persons, rejected by selective service, should have their cases reviewed by a physician rather than by a lay person before they go into industry. This recommendation was seconded by a councilor. Dr Homans asked if this called simply for an expression of opinion by the Council. Dr Browne replied in the affirmative. It was so ordered by vote of the Council.

Committee to Aid the Boston Medical Library—
 Dr. William H. Robey, Suffolk, chairman

In the absence of Dr. Robey, the report was read by the Secretary, as follows:

It is the unanimous opinion of the Committee on Society Headquarters of the Massachusetts Medical Society that it is inadvisable to consider at the present time the purchase of a headquarters house for the Massachusetts Medical Society. Fellows in and out of Boston not members of the Committee have been asked about the desirability of having a house for the Society and not one has been found who has favored such an idea.

During the last six or seven years the Massachusetts Medical Society's use of the facilities offered by the Boston Medical Library has greatly increased, thereby causing added expense to the Boston Medical Library. The Library is used by members of the Society and almost constantly by the editorial staff of the *New England Journal of Medicine*, since all the communications to the *Journal* and especially the references to medical literature are confirmed in the Library.

The Boston Medical Library is the fourth largest medical library in the United States and therefore the thought that it must come to an end because of lack of funds cannot be tolerated. Various ways have been considered for increasing its membership but none have been successful largely because of the lack of interest of practitioners who live at a considerable distance from Boston. Even the membership of fellows living in Greater Boston is much smaller than it should be. The Committee on Finance proposes using the income of the Headquarters Building Fund for the Library. That income has varied in recent years from \$1800 to \$2200 per year. The money would probably be used to make the Library staff more efficient. There is a great need for training in library methods an assistant director who, if he proved to be of the right caliber, might in time be advanced to the position of director. An energetic young man in such a position would undoubtedly find the means of making the Library of far greater service to the members of the Massachusetts Medical Society than is the case at the present time. Those librarians who have been consulted in this matter are agreed that the value of many medical libraries has been greatly enhanced through the efforts of a director trained in modern library methods.

The Massachusetts Medical Society, the *New England Journal of Medicine* and the Boston Medical Library are inseparable. Medical schools and hospitals in many instances have their own working libraries, but the Boston Medical Library is and will continue to be the greatest reference library in this section of the country. We have the expectation of acquiring before long some additional space in the Library building which can be used for meetings of committees and other groups.

The Secretary pointed out that this report contained a recommendation that the income from the Headquarters Building Fund, amounting to between \$1800 and \$2200 per year, be turned over to the Boston Medical Library as a means of keeping

this valuable institution going. The Secretary moved the adoption of this recommendation and said that Dr. David Cheever, who likewise was unable to be present, wanted to be recorded in its favor. The motion was not seconded.

Dr. Charles E. Mongan, Middlesex South, objected to the adoption of this recommendation on the grounds that it calls for action that more properly should come under new business. He added that it came to us all as news that this situation had arisen. He moved that the whole matter be referred to the Executive Committee, that the attention and study which it deserves be taken by it and that its report be given at least twenty days before the annual meeting if it is possible to do so. This motion was not seconded.

Dr. Homans said he rather agreed with Dr. Mongan's idea. He added that from the point of view of the Committee on Finance, this matter of using some of the income of so-called funds for a permanent home has rather appealed to him. The income from funds of this kind that have been accumulating for a great while had better be used if some good use of the income can be found. If the dollar is devaluated 65 per cent the fund would not be what it was. So far as the Library is concerned, Dr. Homans added that he was one of its several directors and that the idea of this institution has always been to serve the Massachusetts Medical Society. Dr. Homans quoted Mr. Metcalf as saying that some attempt should be made to sell the Library to the medical public. Dr. Homans added that this has been successfully done in Chicago. The Boston Medical Library needs an active young man to put this over. The Library itself, without being in actual financial straits, is utterly incapable of doing this alone.

Dr. Fitz moved the acceptance of the report. This motion was seconded by Dr. Albert A. Horner, Suffolk, and it was so ordered by vote of the Council.

Dr. Conley asked the source of this \$1800 to \$2200 that it is proposed to turn over to the Boston Medical Library. Dr. Homans replied that it comes from the income of the Building Fund.

Dr. Hunt thought it would be enlightening to know how serious were the financial straits of the Library. Dr. Homans said that the Library was not in financial straits. It could continue to operate. It needed rehabilitation, however, and it did not have the funds to do it.

At this point Dr. Allen G. Rice, Hampden, asked Dr. Mongan to repeat his motion. Dr. Mongan again offered his original motion. It was seconded by Dr. Rice and it was so ordered by vote of the Council.

Committee on Ways and Means to Conserve Physicians' Energies—Dr Elmer S Bagnall, Essex North, chairman

This report (Appendix No 10) said that perhaps one third of the able bodied active practitioners of medicine are now withdrawn from their communities by the war effort. It added, however, that this will not seriously endanger the distribution of essential medical care except in certain areas where mushroomed growth of population has taken place.

It referred to Worcester as one center that had undertaken to utilize the services of hospitals in attempting to locate physicians in matters of emergency.

In Haverhill, physicians have volunteered to respond to night calls when the family physician is not available. For this service physicians are listed for each night and the telephone company is co-operating. The report spoke of the co-operation of a prominent pharmaceutical house in this work. It emphasized the fact that the method of handling this problem will vary with the community and that the medical profession of each community should take this responsibility to itself.

Hospitals should have the co-operation of their staff doctors to the end that hospital beds shall be used only by those who actually need them.

The report emphasized that these problems are very much in the minds of organized medicine and that, so far as Massachusetts is concerned, the Committee on Public Relations, because of the nature of its composition, would seem to be the clearing house for the initiation of remedies.

Dr Fitz commented on the importance of this report. He asked Dr Bagnall if he had any ideas concerning how the views that he put forward could be brought before the public and before the profession most forcibly.

Dr Bagnall replied that he thought that the matter should have a little more study and that the Committee on Public Relations might be able to devise the means of spreading the doctrine. Dr Bagnall continued as follows:

All of you probably saw the editorial in the *Herald* recently, I think about a week ago. It was very good. And there have been editorials in a lot of papers, and magazine articles. *Time* had an article, the *New York Times* had a special article in the Sunday magazine section. The idea is being broadcast, and I think in Massachusetts the whole state needs to consider it rather more than it has as yet. I think we in organized medicine rather tend to let these things go by default. If we are going to be considered by the Government we must do what we can to organize our house and fulfill our obligations in the distribution of medical care, so that they are more likely to consult us than if we default and they have to take over. I don't know that I have any specific recommendations beyond these.

Dr Bagnall moved that this report be accepted as a report of progress and that the committee co-operate with any other agency that may be made available to carry out these suggestions. This motion was seconded by Dr Mongrén and it was so ordered by vote of the Council.

APPOINTMENTS

Dr Schadt read a list of nominations.

Delegates and alternates to the House of Delegates American Medical Association from June 1, 1943 to June 1, 1945

Delegates	Alternates
Allen G Rice, Springfield	Patrick J Sullivan, Dalton
Richard H Müller, Boston	John Tallon, Worcester

Delegates to the annual meetings of the medical societies of the other New England States (except New Hampshire)

<i>Maine</i>	Warren H Sherman, Lowell, and Frank W Snow, Newburyport
<i>Vermont</i>	George D Henderson, Holyoke, and George L Steele, Springfield
<i>Rhode Island</i>	George A Buckley, Brockton, and Howard P Sawyer, Fall River
<i>Connecticut</i>	Ira M Dixon, Stockbridge, and Clarence E Burt, New Bedford

Delegate to the Annual Congress of the American Medical Association on Medical Education and Licensure at the Palmer House, Chicago February 15 and 16, 1943

Reginald Fitz Boston

Ad interim appointments to fill vacancies

COUNCIL

Dr Byron H Porter, Berkshire, replacing Dr I S I Dodd, who has become a member <i>ex officio</i>
Dr Frederick S Hopkins, Hampden, replacing Dr Oliver J Menard, resigned
Dr Benjamin S Wood, Middlesex South, replacing Dr Raymond A McCarthy, resigned
Dr David L Belding, Norfolk South, replacing Dr Robert L Cook, who has become a member <i>ex officio</i>
Dr Frederick W O'Brien, Suffolk, replacing Dr George C Shattuck, resigned
Dr Arthur W Marsh, Worcester, replacing Dr George C Tully, resigned
Dr Alfred P Lachance, Worcester North, replacing Dr Jesse C Hiles, resigned

BOARDS OF CENSORS

Dr George A Buckley, supervising censor, Plymouth, replacing Dr William T Hinson, resigned
Dr John A Putney, member of Board of Censors, Plymouth

COMMITTEE ON ARRANGEMENTS

Dr George G Bailey, replacing Dr Robert H Barker, resigned
--

COMMITTEE ON LICENSATION

Dr Charles D McCann, Plymouth, replacing Dr William T Hinson, resigned
--

COMMITTEE ON WAYS AND MEANS TO CONSERVE PHYSICIANS' ENERGIES

Dr. Elmer S. Bagnall, *chairman*
 Dr. Charles F. Wilinsky
 Dr. John J. Dumphry

Dr. Schadt asked if there were any nominations from the floor. Dr. J. Harper Blaisdell, Middlesex East, moved that they be confirmed. This motion was seconded by a councilor and it was so ordered by vote of the Council.

NEW BUSINESS

The President read the obituary of Dr. Charles Malone, a councilor from Norfolk District.

Dr. Charles Malone, councilor from the Norfolk District, died at his home in Jamaica Plain on October 10, 1942. He was in his sixty-eighth year.

Dr. Malone received his degree from Tufts College Medical School in 1902 and since that time had practiced in Jamaica Plain. He was a fellow of the American Medical Association.

Two sons and a daughter survive him.

At the request of the President, the Council stood in silence for one minute in tribute to the memory of Dr. Malone.

The Secretary presented a letter and enclosure (Appendix No. 11) which he had received from Dr. Henry M. Landesman, Norfolk.

Dr. Mongan moved that these matters be referred to the Committee on Legislation. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Dr. Hyman Morrison, Norfolk, urged greater support for the Boston Medical Library. He urged the councilors to get new members for the Library and suggested that hospital libraries might become participating members.

Dr. John Fallon, Worcester, made the following motion:

That the Executive Committee and the editors of the *New England Journal of Medicine* be instructed to investigate the feasibility of sending the *Journal* to each military station, having a medical library, at the expense of the Massachusetts Medical Society, that the Executive Committee be empowered to act in this matter and that the sum of \$400 be appropriated to that committee for that purpose.

Dr. Richard M. Smith, Suffolk, asked how many copies that would mean. He expressed the view that it might run into a considerable number of *Journals* and that the cost might be great.

Dr. Conley expressed the view that the men at Guadalcanal and Solomon Islands are not going to have much time to read the *Journal*.

Dr. Nye thought 800 copies might be needed and observed that \$400 would not go far under these circumstances.

Dr. Fallon remarked at this point that, in view of what had been said, it would be better if he withdrew the second part of his motion and left that part which empowered the Executive Committee only to look into the matter.

Dr. Homans suggested that the *Journal* ask members to donate journals. He expressed the viewpoint that if this was done many contributions would come in for this purpose.

Dr. Bearse suggested that a notice be printed in the *Journal*, directed to subscribers, asking them to return their journals, after they had read them, for transshipment to the Army libraries.

Dr. Nye expressed the view that probably as many as 75 journals are now going to Army hospitals.

Dr. Fallon's original motion, which was not seconded, was withdrawn by him. He offered the following motion:

That the Executive Committee and the editors of the *New England Journal of Medicine* be instructed to investigate the feasibility of sending the *Journal* to each military station, having a medical library, at the expense of the Massachusetts Medical Society.

This motion was seconded by Dr. Fitz and it was so ordered by vote of the Council.

Dr. Harold R. Kurth, Essex North, made the following statement to the Council:

I wish to draw your attention to a matter which presented itself to the local membership committee of the Essex North District Medical Society. This matter arose in the course of the examination of one of its applicants for membership in the Massachusetts Medical Society just previous to the last censors' meeting. Having presented the facts in this case, I should like to call on the members of the Council for a sense-of-the-meeting vote.

An applicant, who is a graduate of the University of Kansas City Medical School in 1932, licensed to practice medicine in Massachusetts in 1937, applied, on July 17, 1942, for admission to the Massachusetts Medical Society. His application was sponsored by a reputable member of the profession in his community, and forwarded to the district secretary, together with six letters of recommendation from colleagues of high professional standing in this district. The Essex North local membership committee met, examined and interrogated the applicant very closely and, as a result of that examination and close interrogation, was of the unanimous opinion that he should be recommended for fellowship in the Society. I might state here and now that the local membership committee of Essex North takes its work very seriously and investigates all applicants, particularly those of unapproved or foreign schools. Unless they meet its unqualified approval the committee does not hesitate to refuse their applications for membership in the Society. This has been amply demonstrated in the past by the number of applicants who have been refused fellowship in the Society.

The chairman of the central committee on membership was duly notified by the secretary that "it is the

unanimous opinion of this committee, after due investigation, and close interrogation that the applicant be recommended for fellowship in the Society. The local membership committee was somewhat surprised when it received word that the central committee on membership did not approve the application in spite of the fact that it had been unanimously endorsed by the local committee. The reasons given by the chairman of the central committee were that his educational qualifications were rather dubious. The local committee maintains that it already fully realized that situation, but felt, nevertheless, that it was in a better position to pass judgment on the man's qualifications for membership than was a group of men who in all probability did not know him at all. Furthermore, the local committee felt that his educational qualifications would be no different in two years than they were at the present time!

The second reason given by the central committee was that the local committee was not particularly enthusiastic and that his recommending letters were not particularly informative. The local committee in answer to this criticism, states that it feels that it is not necessary for the local committee to eulogize its applicants, and that when the local committee unanimously approves an applicant for fellowship in the Society, it means exactly that, and nothing else. The recommending letters of the applicant were honest expressions of opinions of physicians of high standing in his district, and due emphasis should be placed on these letters of recommendation.

The third criticism as stated by the chairman of the central committee was that it was of the greatest importance that the district membership committee should show that the district society wants that applicant as a member. To this criticism the local committee replies that the Massachusetts Medical Society is representative of the highest standard of medical practice and medical ethics, and is the organization with which all physicians aspire to become identified. Therefore the applicant seeks the Society and not the Society the applicant!

The purpose in presenting this matter to you is that it was felt by the Essex North local committee that it had spent a great deal of time in investigating his man's qualifications, it had spent almost an hour in interviewing this man and as a result had unanimously approved his application. Yet in spite of all this work, and in spite of the fact that this man was endorsed by a group of men for whom the local membership committee has the highest regard his application was rejected by the central committee for the reasons which have been discussed above. It is felt by the local committee that if the opinion of the local committees in general is to be upset by the central committee for such inadequate and unsubstantial reasons, that the function of the local committees will become purely superfluous in character. When Dr John Monks of the Suffolk District, introduced the change in the by laws with reference to application for fellowship in the Massachusetts Medical Society at the special meeting held on April 9, 1941, he stressed in speaking of the local committee, as follows:

The Committee on Medical Education and Medical Diplomas has sensed for a long time how helpful it was in obtaining adequate information on which to determine the desirability of candidates for

fellowship this point has already been discussed more fully in the formal report. It is believed that a local board will be in every way better fitted to obtain this information than the central committee. The number of men on the board is small, they are already in positions of responsibility in their local society, and two of the three are already members of the board of censors, which eventually will examine those candidates finally approved. Further, it is very definitely felt that in the case of graduates of unrecognized schools the essential responsibility of whether or not they should be admitted to membership in the local society should lie with their own nearby colleagues not with those farther afield.

He furthermore stated: The central committee shall take the responsibility of seeing that on the one hand undue pressure has not been brought to bear on the local board to recommend for approval an undesirable applicant nor on the other hand that unwarranted local prejudice bar from approval a desirable applicant. It does seem, then that the responsibility for recommending or turning down applicants for fellowship should rest with the local committee under the supervision of the central committee. I might state furthermore that this was the opinion in the minds of Dr J H Blaisdell's by laws committee in reviewing the mechanism for application for fellowship in the Society. It is the feeling of the local membership committee of Essex North that the principles, as expressed by Dr Monks and Dr Blaisdell's committees, have been disregarded in this case and that should this policy be continued, the important work of local committees will be jeopardized and must eventually become purely superfluous.

We have brought this matter to the attention of the Council because we are firmly convinced that the present by laws for application for membership to the Massachusetts Medical Society are adequate and desirable. An applicant is tried and approved by his colleagues who are in an excellent position to know the type of professional ethics which this applicant practices far better than a group of men who in all probability know nothing of the applicant at all! It is hoped that the principles expressed by Dr Monks will continue to dominate the endorsement of all new applicants to the Society.

Dr Kurth made the following motion:

It is the sense of this meeting that the essential responsibility of whether or not graduates of unrecognized or foreign schools shall be admitted to the Society lies in the local membership committees and that the central committee should concern itself essentially with the responsibility of seeing that no undue pressure has been brought to bear upon the local boards either to endorse or to bar, the approval of candidates.

Dr Bagnall in seconding the motion said the issue was clear. Either the local committee should do the job it ought to do or else the local committee should be discarded.

Dr Roy V Brackett, Essex North, spoke of how carefully the applicant had been examined and

how thoroughly the question of his acceptance had been discussed. He said that no change in the by-law is desired. The by-law is entirely adequate. Its administration, however, requires some attention.

Dr. Norman A. Welch, Norfolk, called the attention of the Council to the fact that, while the present by-laws were in the making, he tried to provide a means of appeal to the Executive Committee in cases of this sort. He added that he does not think this situation will arise often but, when and if it does, there is no means of handling it.

Dr. Fitz asked for a reading of the by-laws as they relate to this matter.

Dr. Schadt read from the by-laws as follows:

The Committee on Membership shall have custody of such documents so long as needed and then shall deliver them to the custody of the Secretary; they shall remain *confidential*.

The Committee on Membership shall consider the application of each applicant approved for censors' examination by a board of membership. It shall determine finally whether or not such applicant may take that examination.

The Committee on Membership shall not consider the application of any applicant disapproved by a board of membership except on the written request of a majority of that board of membership.

Dr. Mongan asked for a rereading of the motion. Dr. Kurth complied and added that he did not propose any change in the by-laws and that his motion was not in conflict with these laws. He simply wished to determine the meaning of this new mechanism that has been set up—in other words, whether the responsibility of determining if a man is eligible lies with the local committee or with the central committee.

In answer to Dr. Blaisdell, Dr. Kurth said that all he was trying to get by his motion was the sense of the meeting.

Dr. Fitz expressed the thought that there were not enough councilors present at this time for the Council to pass a sense-of-the-meeting vote. There was some discussion at this point about a quorum. This issue, however, was not formally raised.

Dr. Kurth withdrew his motion and Dr. Bagnall his second with the consent of the Council.

Dr. Mongan moved that further discussion on this matter be postponed to the next meeting and that this matter be made the first order of business. This motion was seconded by a councilor and it was so ordered by vote of the Council.

Dr. Mongan moved that the Executive Committee consider some method of attendance that would cause councilors to remain until the business of the Council is completed. Dr. Fitz seconded the motion.

In supporting his motion Dr. Mongan referred to the meetings of the House of Delegates of the American Medical Association. He pointed out that each delegate was required to sign an attendance slip at every session and that the record of attendance was published, so that it might become generally known who were and who were not attending to their duties. He added that this had a salutary effect.

The motion was adopted by vote of the Council. The Council adjourned at 3:30 p.m.

MICHAEL A. TIGHE, *Secretary*

months ended December 31, 1941, made by Messrs. Hartshorn and Walter, of Boston, has been submitted to the attention of the Auditing Committee.

As the Auditing Committee, we have carefully examined the report of these certified public accountants, and approve the figures submitted by them.

LEROY A. SCHALL, *Chairman*
JOHN ROCK

* * *

January 30, 1942.

The Auditing Committee:

Dr. LeRoy A. Schall
Dr. John Rock

The Massachusetts Medical Society

9 The Fenway
Boston, Massachusetts

Gentlemen:

At the request of your treasurer, Dr. Charles S. Butler, we have examined the books and accounts of the Massachusetts Medical Society for the twelve months ended December 31, 1941, and submit herewith:

SCHEDULE A: Statement showing the balance sheet of the Massachusetts Medical Society, December 31, 1941.

SCHEDULE B: Statement showing the revenue and expenses of the Massachusetts Medical Society for the twelve months ended December 31, 1941.

The cash balance on December 31, 1941, was verified by direct correspondence and reconciliation. The cash receipts as recorded have been deposited in the bank and disbursements are supported by vouchers or canceled checks.

The securities and savings-bank books were examined or accounted for.

The accompanying balance sheet and related statement of revenue and expenses fairly present the position of the Massachusetts Medical Society on December 31, 1941, and the results of operations for the year ended on that date.

Respectfully submitted,
HARTSHORN AND WALTER.

50 Congress Street
Boston

APPENDIX NO. 3

REPORT OF AUDITING COMMITTEE FOR YEAR ENDED
DECEMBER 31, 1942

We have examined a statement made by Hartshorn and Walter, accountants and auditors, 50 Congress Street, Boston, submitted to us January 28. They state that they have verified the cash balance by direct correspondence and reconciliation; that the cash receipts as recorded have been deposited and that disbursements are supported by vouchers or canceled checks; and that the securities and related statement of revenue and expenses fairly present the position of the Society on December 31, 1942, and the results of operations for the year ended on that date. They have submitted a statement showing the balance sheet of the Society on December 31, 1942, and a statement showing the revenue and expenses for the Society for the twelve months ended December 31, 1942. There is nothing in the statements concerning the investments made or closed during 1942 or whether there is an increase or decrease in the capital investment.

The by-laws state that the duty of the Auditing Committee is to require examination by a certified public accountant of the assets and securities of the Society in the custody of the Treasurer and the Treasurer's books and accounts. We have talked with the Assistant Treasurer and he has assured us that Hartshorn and Walter have done this thoroughly.

It is also the duty of the Auditing Committee to verify the accountant's examination. In so far as above stated,

we have "verified" the accountant's examination. We have not examined the Treasurer's books and accounts nor have we checked the actual assets and securities of the Society.

If the duties of the Auditing Committee as interpreted by the Council are to review the report of the certified public accountant as submitted in order to save the Council's time, the committee believes that it has performed its function. If the duties of the Auditing Committee as interpreted by the Council are to afford assurance to the Council that the finances of the Society are adequately protected, we have not in our opinion fulfilled them. We have been assured that, in the past, auditing committees have confined their work to what we have done.

It is our unverified opinion based on conversations with officers in the Society and a study of the by-laws pertaining to finances and a study of the accountant's report for the year ended December 31, 1942, that the finances of the Society have been and are well administered but that this is due to the unusual ability and devotion of the officers concerned. We do not believe that the Society can feel that its funds are protected by the by-laws. We believe that investments should be under the direction of a professional investment company, and that the report of the accountant should be more complete and include a list of investment transactions. It should also include a statement that the report for the current year is reconciled with the report of the preceding year.

We believe that the duties of the Auditing Committee could better be discharged by a business man trained as a bank examiner.

FRANCIS COOLEY HALL, *Chairman*
BURTON E. HAMILTON

* * *

January 29, 1943

The Auditing Committee:

Francis C. Hall

Burton E. Hamilton

The Massachusetts Medical Society

8 The Fenway

Boston, Massachusetts

Gentlemen:

At the request of your treasurer, Dr. Charles S. Butler, we have examined the books and accounts of the Massachusetts Medical Society for the twelve months ended December 31, 1942, and submit herewith:

SCHEDULE A: Statement showing the balance sheet of the Massachusetts Medical Society, December 31, 1942.

SCHEDULE B: Statement showing the revenue and expenses of the Massachusetts Medical Society for the twelve months ended December 31, 1942.

The cash balance on December 31, 1942, was verified by direct correspondence and reconciliation. The cash receipts as recorded have been deposited in the bank and disbursements are supported by vouchers or canceled checks.

The securities and savings-bank books were examined or accounted for.

The accompanying balance sheet and related statement of revenue and expenses fairly present the position of the Massachusetts Medical Society on December 31, 1942, and the results of operations for the year ended on that date.

Respectfully submitted,
HARTSHORN AND WALTER.

APPENDIX NO 4

REPORT OF THE TREASURER

It is unfortunate that Dr Butler cannot be with us to present the Treasurer's report for 1942, but his illness has made this impossible. It has also prevented his compiling a report.

Therefore I am simply submitting the bare figures for 1942 without any personal comments.

In 1942, revenues from resident dues were \$49,182 39 as compared with \$49,779 00 from the same source in 1941. Nonresident dues were \$1738 25 as compared with \$1670 75 in 1941. The combined annual dues were there for \$50,920 64. Other revenues were as follows from invested funds (not including the Building Fund), \$3932 12, from sales, \$17 30, from profits on securities sold, \$288 65, from booths at the annual meeting, \$3287 75, received for the *New England Journal of Medicine* from fellows in active service, \$139 80, and from examinations by censors, \$558 00. Hence the total revenue to the Society amounted to \$59,144 26, an increase of \$1444 96 over 1941.

The Building Fund received an income of \$1844 19 and profit from sales of securities amounted to \$72 66. The total Building Fund now stands at \$63,991 80.

In 1942, total expenses were \$48,680 84, with an unexpended revenue of \$10,463 42 as compared with total expenses of \$45,310 47 and an unexpended revenue of \$12,388 83 in 1941.

The Society ends 1942 with total assets of cash and securities of \$229,951 27, and unexpended revenues of \$10,463 42.

ELIOT HUBBARD, JR., Treasurer pro tempore

APPENDIX NO 5

REPORT OF THE EXECUTIVE COMMITTEE

The Executive Committee of the Council has had two meetings since its report to the Council in October. The first of these was held on October 21, 1942, and the second on December 30, 1942.

The October meeting was of an emergency character. It was called for the purpose of giving consideration to a proposition advanced by the Massachusetts Board of Registration in Medicine as the result of a conference that this Board had with Dr. Frank H. Lahey, chairman of the Procurement and Assignment Service, Dr. Reginald Fitz, Massachusetts chairman of this agency, Dr. George Leonard Schmidt, Dr. Roger I. Lee and the Secretary.

The proposition is briefly stated in a vote which was adopted by the Board of Registration in Medicine, on October 14, 1942.

Voted to ask the Governor of Massachusetts to waive the law (Chapter 112, Section 2, T. E.) to the effect that we may temporarily permit members of the medical profession, who are graduates of approved schools, who are registered to practice in other states and who are recommended by the National Procurement and Assignment Service, to practice in Massachusetts during the emergency without payment of the registration fee, and without examination.

This action on the part of the Board grew out of representations made by the National Procurement and Assignment Service, through its chairman, Dr. Frank H. Lahey.

This agency in these representations stated that its objectives were twofold: to supply the armed forces with physicians, dentists and veterinarians and at the same time to provide sufficient numbers of these groups to care properly for civilian needs.

These representations went on to speak of some of the difficulties with which the agency was meeting in maintaining adequate medical care for civilians in certain parts of our country. One of these had to do with such strictures laid down by state licensing laws as prohibited a physician licensed in one state from practicing his profession in another without first fulfilling all the requirements—examination and so forth—of the second state.

If certain parts of these laws might be modified or waived for the duration of the emergency, the job of procurement and assignment would to this extent be made easier.

Dr. H. Quimby Gallupe, secretary of the Massachusetts Board of Registration in Medicine, was present at the meeting of the committee. He explained that, when the action of the Board was called to Governor Saltonstall's attention, the latter expressed his willingness to use his wartime emergency powers in this direction provided the approval of the Massachusetts Medical Society was obtained.

It was unanimously voted by the Executive Committee to approve this act of the Massachusetts Board of Registration in Medicine.

The actual drawing up of such an act is the duty of the Attorney General. When this matter was placed before the latter, he advised against it because he could not be convinced of its need in Massachusetts at that time. He expressed himself, however, as without prejudice against the time when the need might arise in this state. He also spoke of the possibility of legislative enactment along these lines.

The Executive Committee has also given consideration to this latter course of action, particularly since the receipt by the Secretary on December 10, 1942, of a communication from the Federation of State Medical Boards, acting through its executive committee in joint conference with the Directing Board of Procurement and Assignment Service. This letter includes a draft of proposed legislation and a statement of certain principles which should govern it.

The Executive Committee, at this time, recommends adversely in the matter of seeking in Massachusetts legislative action to this end. It does so because it believes the Legislature is sure to ask the same question as did the Attorney General as to the need of modifying the law at the present time in this state and because a directive from the Governor, when and if such a need develops, is much the simpler approach.

The Executive Committee, acting on the recommendation of the Committee on Membership, has

(1) Retired the following fellows:

James Alfred, Brockton
William G. Curtis, Wollaston
Stephen R. Davis, Lynn
Charles Dudley, Kingston
Everett V. Hardwick, Milton
Charles H. Hare, Boston
John F. Jordan, Peabody
J. Herbert Libby, Weymouth
Robert G. Loring, Concord
Charles J. Spaid, Springfield
John J. Sullivan, Dorchester

(2) Restored the following physicians to fellowship provided all their obligations to the Society are discharged within one month:

Frederick W. Celce, Holyoke
Henry A. Dunphy, Palmer
Benoit W. Garneau, Fall River
Bert B. Hershenson, Brookline
Thomas H. Kenney, Northampton
Charles Liebman, Brookline
John J. Sullivan, Dorchester
David Zacks, Brookline

(3) Accepted the resignations of the following fellows:

Harold D. Chope, Brazil (with remission of dues)
Harold I. Gosline, Amarillo, Texas
Grosvenor B. Pearson, Pittsburgh, Pennsylvania
Harry A. Warren, Champaign, Illinois

The Executive Committee has reviewed the report of the Committee on Membership as it refers to a former member who was asked to resign and who now seeks restoration to fellowship. The Executive Committee recommends the adoption of this report.

The Executive Committee has reviewed the budget for 1943, presented by the Committee on Finance, and recommends its adoption.

The committee has reviewed the report of the Committee on Public Relations and recommends the adoption of its recommendation.

The committee has reviewed the report of the Committee on Medical Education, anent the nursing situation. It commends this report to the attention of the Council.

The committee reviewed the report of the Committee on Arrangements and approves the recommendations contained therein.

The President was in receipt of the following communication from Dr. Reginald Fitz, Massachusetts chairman of Procurement and Assignment Service:

Office of Defense Health and Welfare Services
Procurement and Assignment Service
Office of State Chairman
319 Longwood Avenue, Boston

December 7, 1942

Dr. George L. Schadt
44 Chestnut Street
Springfield, Massachusetts

Dear Dr. Schadt:

A curious finding has arisen which it seems to me deserves consideration. Approximately 1900 Massachusetts doctors (1942 *American Medical Directory*) have commissions or have had commissions with honorable discharge in one of the branches of the armed forces. Of these 1900, only 1050 are members of the Massachusetts Medical Society. Of the 850 commissioned officers who are not members of the Society, 200 in round numbers are substandard school graduates and not necessarily

desirable for the Society to worry about. That leaves a pool of about 650 young men who represent sort of a float ng medical populat on.

In th s pool are interns residents fellows jun or teachers in medical schools who come here for two or three years and such people. Potentially in normal times they represent a valuable part of our medical populat on because practically all are engaged in full time work or are active in research or teaching. I raise the quest on whether the Society and the Boston Medical Library might not make some effort to attract men of this type.

Could we not offer some sort of a jun or or temporary membership p to both organizat ons at a reduced fee and would it not be worth while for these organizat ons to stir themselves up in order to make the work as appealing as possible to men of this type? What is your thought on the matter?

As ever

REGINALD FITZ, M.D. Chairman
Massachusetts State Committee

The committee recommends that this matter be referred to the Committee on Membership.

The Secretary was in receipt of a telegram from Dr. Olin West, secretary of the American Medical Association, recommending the creation of a committee in the Massachusetts Medical Society to be known as a War Participation Committee. The committee recommends that the President be authorized to appoint a committee of five to serve this purpose.

The President was in receipt of a letter from Dr. Charles S. Butler, treasurer of the Massachusetts Medical Society, requesting an indefinite leave of absence because of ill health. The committee recommends that Dr. Butler's request be granted, that the Council express its great thanks for his fine service to our organization and its regret that he has found such a step necessary.

The committee approves of the recommendation of the Committee on Finance that Dr. Butler's salary be paid to him up to and including December 31, 1942.

The committee also approves of the recommendation of the Committee on Finance with regard to the figure set as compensation for the Treasurer *pro tempore*.

The President received the following letter:

December 30, 1942

Dr. George W. H. Schadt, President
Massachusetts Medical Society
Boston, Massachusetts

Re: Gift to Massachusetts Medical Society

Dear Doc:

Enclosed please find my check for \$1000 as a gift to the Massachusetts Medical Society to be used in carrying out its usual functions as an educational body.

I would suggest that—though I do not make a binding condition of the gift—it is I find be used to procure any necessary lunches for the official meetings of the Committee on Ethics and Discipline. I have in mind the many hours spent and the difficult problems dealt with not lastly at such meetings.

Please advise me whether the Society will accept this gift.

Sincerely

WILLIAM J. BRICKLEY, M.D.

The committee offers three recommendations with regard to this gift:

- (1) That it be accepted by the Council with thanks.
- (2) That it be used to create a fund which shall be known as the Dr. William J. Brickley Fund.
- (3) That it be used for the purpose outlined in Dr. Brickley's letter until otherwise ordered by the Council.

The President announced to the committee certain *ad interim* appointments. These appointments, which will be read later in the meeting, have the approval of the committee.

MICHAEL A. TIGHE, Secretary

APPENDIX NO. 6

REPORT OF THE COMMITTEE ON PUBLICATIONS

The committee has secured to deliver the Shattuck Lecture at the annual meeting of the Society in May, 1943, Dr. George W. Thorn Hersey, Professor of the Theory and Practice of Physics at Harvard University and physician-in-chief at the Peter Bent Brigham Hospital.

The committee has continued to supervise the publication of the *New England Journal of Medicine*. Under the able editorship of Dr. Robert N. Nye, the *Journal* has maintained its high quality as one of the leading medical publications in this country. The Society has reason to feel proud of the *Journal*. That the *Journal* is valued outside of the Society is evidenced by the increasing circulation among nonmembers.

We quote from Dr. Nye's report to the committee:

During 1942, the *New England Journal of Medicine* received 1984 new 'outside' subscriptions, a total that is over 50 per cent greater than the total received in 1941. Of these subscriptions, 1085 were from regular subscribers and 899 from medical students. As would be expected, there were many cancellations, undoubtedly owing to enlistment in the armed forces, the net increases were 216 regular subscribers and 711 medical students, which total 927. As of December 31, 1942, *Journals* were being sent to 5083 members of the Society (a decrease of 74 from the 1941 figure), 3462 regular subscribers and 1193 medical students, a total of 9738, which is greater by 853 than the total for 1941. This does not include 348 members of the New Hampshire Medical Society, who receive the *Journal* once a month.

The editorial board took action on 238 manuscripts during 1942, a decrease of 90 compared with the figure for 1941. Of these papers, 169, or 71 per cent, were accepted.

Operations for the year resulted in a net loss of \$17,550 which is approximately \$2450 less than the amount appropriated by the Society. The net cost per member of the Society was \$343, as compared with \$320 in 1941. There was an increase in operating expenses due to the larger circulation, the increased cost of binding and mailing, and the fact that in 1942 fifty-three issues of the *Journal* were distributed which happens every seven years, when January 1 falls on a Thursday.

It is difficult to predict what will happen in 1943. Undoubtedly the number of member subscribers will be decreased owing to their enlistment in the armed forces; on the other hand it seems likely that the number of outside subscribers will hold its own or possibly show a slight increase, in spite of cancellations. Expenses should decrease as a result of lower publication costs (provided the total circulation is smaller) and an increase in advertising revenue owing to higher rates which became effective on January 1. The decrease in the number of manuscripts submitted for publication may become a serious problem, in any event, the pagination of the *Journal* will be cut down, since the members of the editorial board believe that the high standards for acceptance should not be lowered. One typist, and probably two, must be added to the office staff, owing to the increased demands of the Society. This, however, will not increase the operating

costs of the *Journal*, since the Society pays for its share of expense.

An abstract of the auditor's report is attached as a part of the report of the committee.

JAMES P. O'HARE
CONRAD WESSELHOEFT
WILLIAM B. BREED
RICHARD M. SMITH, *Chairman*

*According to agreement with the Committee on Finance that the cash balance of the *Journal* shall not exceed \$6,000.

It is recommended by the Committee on Membership that the following recommendation from the then Committee on Membership passed by the Council on February 5, 1941, be revoked: "Fellows of the Society who are called to full-time service in the United States Army, Navy or Public Health Service during the present emergency and whose livelihood is thereby impaired may, on written application to the Treasurer stating their situation, have their dues remitted for the year of service. A period of full-time service greater than six months shall give the privilege of a year's remission of dues. The *New England Journal of Medicine* will be sent to such members only on payment of an annual fee of four dollars (\$4.00). The president of the Society shall determine the end of the present emergency."

The following recommendation in regard to members of the Massachusetts Medical Society is urged. "Fellows of the Massachusetts Medical Society who have enlisted or been called to full-time service in the United States armed forces or in the United States Public Health Service during this present war shall have no further dues collected for the duration, their names continued on the membership roll of the society as active members in good standing, and to only such members as request it will the *New England Journal of Medicine* be sent and then only on payment of an annual subscription fee of \$4.00 per year. Any members who have joined or who subsequently join the United States armed forces or the United States Public Health Service should advise personally or by some means the treasurer of the Society to facilitate omission of dues. 'For the duration' is interpreted as meaning honorable discharge from the United States armed forces or United States Public Health Service."

It is recommended that a flyer of this recommendation be attached to every bill or communication relating to indebtedness sent from the Treasurer's Office of the Massachusetts Medical Society to its members.

HARLAN F. NEWTON, *Chairman*

APPENDIX NO. 7

REPORT OF THE COMMITTEE ON MEMBERSHIP

The Committee on Membership, meeting with the supervising censors and in consultation with the Board of Membership of Suffolk District Medical Society together with the Committee on Ethics and Discipline, recommends that the application for reinstatement of Dr. Morris A. Cohen, 452 Beacon Street, Boston, this former fellow's resignation having been requested by the Committee on Ethics and Discipline, shall under the provisions of Chapter I, Section 11, be denied.

The Committee on Membership has received and carefully considered the nomination for honorary fellowship of Dr. Walter Fenno Dearborn by two fellows of the Middlesex South District Medical Society. Dr. Dearborn has gained renown through his achievements and research work in psychology and education at the University of Chicago, University of Wisconsin and now at Harvard University. As director of the Psycho-Educational Clinic of Harvard University he has made noteworthy advancements to arts and sciences and he is already famous for accelerating slow readers. Under the provisions of Chapter I, Section 4, of the by-laws, the Committee on Membership recommends to the Council that associate fellowship be conferred on Dr. Walter Fenno Dearborn, 79 Fresh Pond Parkway, Cambridge, because of his eminent work in the allied sciences.

APPENDIX NO. 8

REPORT OF THE MASSACHUSETTS COMMITTEE, PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS

Your committee has completed a year of active service under war conditions. During the year 1942, and up to January 15 of this year, 3743 Massachusetts physicians were classified. Massachusetts is credited with having 4366 doctors under forty-five years in age. Practically, therefore, most of our doctors of military age have now been examined by local Procurement and Assignment committees, and have been reported to the central committee in Washington as "available" for military service or "essential" to civilian needs. To accomplish such a task has been time consuming and has required hard work and great patience. Your committee is grateful to each member of each local committee for his assistance.

An analysis of our 3743 clearances brings out interesting information. A summary is as follows: 1477 commissioned in Army (39 per cent); 443 commissioned in Navy (12 per cent); 542 declared "essential" (14 per cent); 373 applied for commissions but rejected (10 per cent); and 908 declared "available" but have not applied for commissions (24 per cent).

It is believed that 2048 physicians from Massachusetts are now serving in the armed forces or have received

honorable discharge therefrom. For in addition to the 1920 officers cleared through your committee and commissioned, are the names of 128 physicians credited to Massachusetts by Washington who obtained commissions without clearance or whose clearance forms have been mislaid.

From time to time Massachusetts has been reprimanded for tardiness in filling its hypothetical quota of physicians needed for military use. The calculations involved in determining the quota are complicated. For example, a number of men listed in the *American Medical Directory* as belonging to Massachusetts may have Selective Service boards in other states, and, conversely, a number of young Massachusetts physicians with local boards here may have been at work outside of Massachusetts and may have been cleared through state committees elsewhere. The figures reported here deal with your committee's personal experience and with doctors listed as at work in Massachusetts according to the two latest directories. The committee believes that these figures illustrate the problem which Massachusetts faces. Each doctor on our records who is in the service has been withdrawn from the State and the position that he occupied in our civilian medical society must be filled by another or be done away with.

Either through letter or by personal interview we have heard from the majority of the 908 men declared available but who so far have not applied for commissions. A variety of reasons, each one logical enough, are brought forward by men who do not wish to volunteer: reasons of economy, or of a family nature, or because a man simply thinks that his talents at present are more useful to the community in which he lives than anywhere else. Your committee has attempted to deal with each case as fairly as possible. Every physician who has been interviewed has appeared to wish to do what is right and to determine this wisely has always been difficult.

From the 2293 men who were commissioned or who applied for commissions and were rejected, the following information has been tabulated: 1477 commissioned in Army (64 per cent), 443 commissioned in Navy (20 per cent), and 373 applied for commission but were rejected (16 per cent).

These figures demonstrate that in Massachusetts the ratio of Army to Navy commissions is about 3:1 and that our rejection rate is in the neighborhood of 16 per cent. Our relatively high rejection rate is due in part to the large number of graduates of substandard domestic schools or foreign schools who are licensed to practice in Massachusetts.

The substandard school problem was of considerable interest to the Society a year ago. An analysis of the fate of 200 such graduates who applied for commissions was made. Of these, 70 per cent were commissioned, 9 per cent were regarded as essential and 21 per cent were rejected. Of all Massachusetts physicians who have entered the armed forces, 11 per cent have been graduates of foreign or substandard domestic schools. It is obvious that the credentials of graduates of our domestic substandard schools and of foreign schools have been weighed carefully in Washington and that great care has been employed in deciding which applicants should receive the honor of a responsible post in the care of soldiers.

On many occasions during the year, your committee has been asked how many members of the Society were in active service. At the present moment (January 15, 1943) of 2048 Massachusetts physicians whom we believe

to have been commissioned, only 1122 (55 per cent) are members of the Society. This appears to be due to the fact that young doctors seem in no particular hurry to join the Society. Under ordinary circumstances Massachusetts has proved an admirable training ground and there is a floating medical population of young men who stay here for various lengths of time in some junior capacity. They have an intern's license to practice, they may take the

FIGURE 1

State Board examinations or they may have been certified by the National Board of Medical Examiners. Being uncertain as to where they will settle permanently, they do not take an interest in the affairs of the Massachusetts Medical Society, and besides, they are poor and busy, and have plenty of staff meetings and public lectures to attend. The committee hopes, when the war ends, that a method can be devised to attract such young men into some type of membership in the Society. They have users that are worth cultivating.

The experience of the year has been analyzed in a variety of ways in order to develop more detailed information by which to attack the work of 1943 with intelligence. Your committee has been informed by Dr. Lahey, that approximately 400 more doctors must be withdrawn from Massachusetts during 1943 to meet our quota. The type of doctor most urgently needed is the one who is young, preferably under thirty-eight years old.

On Figure 1, the solid line tabulates by counties the number of doctors who are less than sixty-five years old and the dotted line the number of men in each of the counties believed to be commissioned. On the whole, as

can be seen, all over the State there has been a striking parallelism in the ratio between the total number of doctors and those commissioned. Barnstable County appears to have been overgenerous, but otherwise each county

Finally, a chart has been constructed wherein is listed each town and city in the State, its population, its doctors, and the number commissioned, declared available, essential or unclassified. Of course the figures change

DOCTORS IN MASSACHUSETTS ACCORDING TO SIZE OF POPULATION

FIGURE 2.

appears to have given physicians to the armed forces in about equal proportions. This is a gratifying result.

It seemed of interest to study in greater detail the trends of medical population in cities of different size. With this idea in mind, cities of differing population were analyzed, the doctors of five cities in each group being averaged for those cities with a population up to 100,000; and for three larger cities, Springfield, Worcester and Boston were selected. In order to make results comparable, the physician numbers were expressed in numbers of doctors to 100,000 population. The doctors were broken down into "commissioned," "rejected," "essential," "available" and "unclassified" groupings. The resultant graph (Fig. 2) illustrates what appears to be a consistent trend: the larger the city, the greater in it is the concentration of medical talent. This fact is easily credible for in general the large city in a given locality has several hospitals, acts as consultant to the surrounding territory and thus, by necessity, requires more numerous and highly trained medical manpower than does the small city.

The chart illustrates another peculiarity with which the committee is familiar. The smaller the city, the more is taken as gospel the word "available"; the larger the city, the easier it is for "available" men to do nothing, unwilling to acknowledge that if they left, as Koko sang in the Mikado, "They'd none of 'em be miss'd."

On the other hand, if one takes the trouble to figure out proportions, the proportion of officers to doctors in the different cities is reasonably constant: areas thinly populated have not been allowed to become depopulated medically, except in rare and isolated instances.

from day to day, but the chart serves a useful purpose in helping your committee to visualize at a given time the ever-changing medical picture.

From all these data, it is possible to predict with reasonable accuracy, the fairest source of the 400 doctors who should be commissioned in 1943, taking into consideration population densities of cities and towns, and numbers of doctors. At this writing the most delinquent areas appear to lie in Suffolk, Berkshire, Essex and Hampden counties, with Barnstable too generous (Table 1). There

TABLE 1. Data on Physicians by Counties.

COUNTY	TOTAL PHYSICIANS UNDER 65	THEO- RETICAL QUOTA	PHYSICIANS COMMISS- SIONED	CREDIT OR DEBIT
Barnstable	42	17	28	+ 11
Berkshire	156	70	22	- 48
Bristol	302	110	96	- 14
Essex	499	200	153	- 47
Franklin	46	18	11	- 7
Hampden	379	152	126	- 26
Hampshire	79	32	30	- 2
Middlesex	898	383	367	- 16
Norfolk	398	207	209	+ 2
Plymouth	143	57	52	- 5
Suffolk	2332	882	643	- 239
Worcester	504	202	181	- 21

are various factors responsible for this, the most obvious one being the distribution of men who have applied for commissions but have been rejected. A man may apply for a commission and not receive it. It takes an appreciable time for this to be recorded and even longer for a man previously called "essential" to be declared "available" be-

cause a man previously 'available' has been rejected and thus is not liable to be taken out of the community. More over, interwoven with such a simple arithmetical problem in numbers is the more elusive one of quality. One well trained essential young man cannot be released even though ten imperfectly qualified physicians from his area apply for commissions and are found unacceptable to the Surgeon General.

If the table is actually filled according to this computation, each part of the State will do its proportionate share in sacrifice of medical care, there will be no depletion, and yet, the curve of doctor population ratio in cities of differing sizes shown in Figure 2—which the Common wealth has found satisfactory in times of peace—will be maintained.

It will not be an easy matter to procure the number of officers expected by Massachusetts in the next few months, for by now most of our young physicians wishing to obtain commissions have done so. On the other hand, Massachusetts is fortunate in having a large supply of doctors so that we can well afford to fill our quota and moreover, we are blessed with the heritage of patriotism.

APPENDIX NO 9

REPORT OF THE COMMITTEE CONCERNED WITH PREPAYMENT MEDICAL CARE COSTS INSURANCE

I shall make a report of progress in regard to the Blue Shield.

The first matter concerns the enrollment of participating physicians. At the present time there are between 3300 and 3500 out of 4700 active physicians in the State who have enrolled. When I say 4700, that is an estimate of the men who are eligible to become participating physicians, excluding the men in the services, the men who are in institutions, the men who are in various state departments and the men who have retired. That figure is an estimate that I had from medical headquarters. So that gives a large percentage of participation.

This question of enrollment of physicians is directly related to the question of sales of the contracts, because the general rule through the country, on general medical care programs, is that it is not safe from the viewpoint of physician participation to begin local sales of the contract until there is at least 50 per cent participation by local physicians. Now, starting with our program, I think our problem is somewhat different. There is apparently need of satisfactory participation by the men to take care of the different services provided for in the first surgical obstetrical contract, in the various institutions in the districts. What delay has been encountered comes from trying to secure the enrollment of participating physicians so that all districts will be covered. A beginning of sales has been started in the Boston section because of the generous enrollment of the men there. Offhand it can be said I believe, that all the services are adequately covered in the hospitals in the main centers throughout the State.

There has been a request that local professional service committees and the salesmen (laymen) who will be re-

tive in trying to contact the many doctors who, said they will participate but have not yet signed. Their work can be facilitated greatly if that committee helps them in their approach to the members. They have lists of the men who have not yet sent in their contracts. They have a difficult problem because of gas rationing, which has been the main factor in delaying matters so far. Whatever help can be given locally will be greatly appreciated.

Just one last statement in regard to our approach to this matter on the basis of the partial-coverage contract. We have naturally been subjected to some criticism in getting our program launched with partial coverage rather than with complete medical-care coverage. That we may stabilize ourselves in this decision we have made, I quote two recent experiences that bear out the wisdom of this.

The first is that at a recent meeting at Chicago, where representatives of medical care plans met, one of the men, from California I believe, said that the approach through complete medical coverage was too idealistic. In Michigan they have definitely stated they have retreated entirely from complete coverage and are starting again on partial coverage. One of the northern New York plans, either Utica or Buffalo, has done the same thing.

I think an impressive thing regarding this matter is a recent announcement in the New York *Herald-Tribune* (January 11, 1943) from Health Group Cooperative, which is supported by funds from several of the large foundations. Their program, in effect, includes nothing more than surgical and obstetrical care in the hospital and home and medical care only in the hospital. In other words, those who comprised one of the major groups in criticizing the profession for not starting out with complete medical care have apparently had to retrench to the point where they leave out medical care in the home and office. From their experience they have found this a difficult problem to handle. I think coming from a group that so actively propagandized for complete medical care as an initial step, this fortifies us in our feeling that we were wise in our approach through a partial-coverage contract.

JAMES C. McCANN, *Chairman*

APPENDIX NO 10

REPORT OF THE COMMITTEE ON WAYS AND MEANS TO CONSERVE PHYSICIANS' ENERGIES

Perhaps a third of the able-bodied active practitioners of medicine are now withdrawn from their communities by the war effort. We freely accept this as in the interest of all the people. In some cities all physically fit doctors under forty-five have volunteered. We believe this will not seriously endanger the distribution of really essential medical care. In isolated instances attention has been focused on exceptions where community growth has mushroomed and it is not unnatural that the supply of replacement physicians lags behind the need. In some urban centers it is not yet apparent that there exists a present or potential shortage of doctors. In some of the medical periodicals reports of the measures adopted by organized medicine to adjust for shortage have been recorded. Some of the communities in Massachusetts have organized plans. Worcester has arranged for coverage of unmet needs for medical service from hospital centers. Each hospital has agreed to try to locate one of the doctors in its section on request. In Haverhill doctors have volunteered

to respond to night calls when the family physician (if there is one) is not able to comply. Physicians are listed for each night, a month in advance. The telephone office is co-operating. They know who is available for calls

PASTE THIS IN YOUR PHONE BOOK

SOON— Rationed Medical Care, Too

Haverhill doctors have responded well to the call from the armed services.

There are not as many able bodied younger doctors for the winter load.

Gasoline and tires must be conserved by the doctor, too.

A committee from the medical society is organizing the profession so that the essential quality of medical care will not be impaired.

Will YOU cooperate by:

Making no unnecessary calls?

Making your choice of a family physician and finding what are his office hours?

Calling his office between seven and eight in the morning when requesting house visits?

Being patient until he gets there? (Urgency of the illness and grouping calls by location must influence decision as to who comes first).

Giving your message to the office attendant unless you need to talk with the doctor personally?

Fevers are usually higher at night. If you postpone your decision to call the doctor until evening his capacity for service is impaired.

Arrangements will be made for someone to cover real needs at night.

FIGURE 1.

which come to them directly. This lessens the burden of potential nightwork and is patterned after the Army system of "officer of the day." Excellent co-operative spirit has been manifest.

The accompanying advertisement (Fig. 1) was published in the local paper and some physicians have had reprints with their own office hours appended. One of the local druggists has distributed reprints with his own endorsement.

We would like to call attention to commercial efforts toward public co-operation. Parke, Davis and Company, for example, have an excellent large display card, as well as folders to fit ordinary envelopes. These are dignified, well done and are available to all physicians.

We believe that the manner of handling the problem when and where it exists will vary with each community rather than with the district society. The medical profession in each community should assume responsibility for distribution of reasonably adequate medical care. This may well include institutional and nursing care as well as increased concern for public-health matters.

We believe that the Society can be a clearinghouse for new and better approaches. The American Medical Association has included this matter in its "Doctors at War"

radio series on a national hookup. We believe that local stations should be encouraged to include "Doctors at War" in their broadcasting programs as a public service. We believe that it may soon become desirable to co-operate with local stations for "flash" broadcasts of local conditions.

We believe that we should inform ourselves concerning and co-operate with hospitals', nurses', dentists' and druggists' adjustments to shrinking personnel and supply.

The matter of rationing hospital beds must be considered. We believe that hospitals can more effectively meet this problem by obtaining the assistance and co-operation of the staff in connection with admissions and demissions. This would demonstrate to the physicians so serving, and through them to the rest of the staff, their own obligation to censor potential admissions.

We like to believe that we have available an organization to apprehend and meet problems of distribution in medical care before they reach the stage of public indignation. Some newspapers have already indicated their belief that organized medicine has defaulted in this instance.

The Committee on Public Relations would seem to be an appropriate clearinghouse to initiate remedies. The chairman of the district committee is the delegate to the central committee. Most districts also have themselves subdivided by cities or community groups. This is highly desirable and we recommend your consideration of this plan of organization. In Essex North a special subcommittee was established in Haverhill for physicians. Another is organizing, with the nurses, a more effective adjustment to the serious shortage of nurses. In Worcester a special committee was established.

We recommend that the Committee on Public Relations be authorized to carry on the work for the Society.

APPENDIX NO. 11

LETTER FROM DR. HENRY M. LANDESMAN

February 2, 1943

Michael Tighe, M.D., Secretary
Massachusetts Medical Society Council
Boston, Massachusetts

Dear Mr. Secretary:

Enclosed please find two resolutions, being introduced in the General Court of the Commonwealth, for the approval by the Council.

One of these petitions deals with an arrangement for general reciprocity with other states, and to start immediate treatment when blood of an individual is positive.

The second petition deals with a plan to reduce the annual incidence of contagious and infectious diseases.

Sincerely yours,
HENRY M. LANDESMAN, M.D.

* * *

FURTHER REGULATING RECIPROCAL RELATIONS OF OTHER STATES IN REGARD TO FILING MARRIAGE INTENTIONS

Chapter two hundred and seven of the General Laws is hereby amended by inserting after section twenty B the following section:— *Section 20C.* A certificate of a

qualified or registered physician of any state whose laws are in substantial accordance with the laws of this commonwealth relative to the filing of marriage intentions, to the effect that such physician has examined one or both of the parties to the proposed marriage, that a serological blood test was made by an approved laboratory of that state, and that such test corresponds with that required by this commonwealth, shall be accepted as, and shall be, a sufficient certificate under the laws of this commonwealth.

When such serological blood test for syphilis is positive a clinical examination with subsequent checkup on blood test is positive the person involved shall be instructed to undergo treatment, either by a qualified physician who is competent to treat syphilis or by one of the clinics authorized by the laws of this Commonwealth and to continue such treatment until cured and discharged.

HENRY M LANDESMAN

PROVIDING A PLAN TO REDUCE THE ANNUAL INCIDENCE OF CONTAGIOUS AND INFECTIOUS DISEASES OF CHILDREN

Chapter one hundred and eleven of the General Laws is hereby amended by inserting after section ninety-one, as appearing in the Tercentenary Edition, the five following sections. Section 91A. It shall be the duty of every parent and guardian of a minor, whenever such minor is ill with any one or more of the following diseases, sore throat, common cold, grippe, measles, chicken pox, mumps, scarlet fever, whooping cough, chills or fever,

stiffness in neck, or rash on body, not to send such child or allow it to go to school unless and until it has been examined by a qualified physician or a physician of the local district board of health, whose duty shall be there upon to inform the parent or guardian that the condition of the child is either noncontagious or infectious, as the case may be.

Section 91B. The department of public health and the local boards of health of each political subdivision of the commonwealth shall respectively provide one or more physicians whose duty it shall be to visit children referred to in Section ninety-one A for the purpose of making diagnosis as to the possibility or probability of the infection or contagion to other children if exposed to the sick child.

Section 91C. Each teacher in each public or private school shall spend not less than five minutes in each school day in instructing the pupils under his charge in regard to covering mouths or noses while coughing or sneezing and as to the necessity of wearing proper clothing in cold or otherwise inclement weather and especially as to wearing rubbers in stormy or slushy weather.

Section 91E. Whoever violates any provisions of sections ninety-one A to ninety-one D, inclusive, shall be punished by a fine of not more than fifty dollars or by imprisonment in a jail or house of correction for not more than one month, or both.

Section 2. This act shall take effect upon its passage.

HENRY M LANDESMAN

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29111

PRESENTATION OF CASE

A twenty-two-year-old single shoe stitcher entered the hospital because of painful stiffness of the left side of the neck and weakness of this arm.

Approximately four months prior to admission the patient began to suffer with frequent brief attacks of burning pain in the left side of the neck and suprascapular region that radiated to the left shoulder, arm and thumb. The pain was exaggerated by movements of the head and seemed worse at night. During the periods of pain she noticed numbness and tingling in the left forearm and thumb and the left hand seemed cold and weak. Two months later she felt a swelling in the left side of the neck that seemed to vary slightly in size from day to day but did not apparently become larger.

The family history was noncontributory. At the age of six years an equinovarus deformity of the left foot was surgically corrected. For several years the patient had suffered with brief attacks of "stiff neck" that spontaneously cleared.

Physical examination disclosed a well-developed uncomfortable young woman who held her neck rigid, with the head turned slightly to the left. There was no atrophy of the scalenus or sternocleidomastoid muscles. The left longus colli muscle seemed atrophied. There was a slight dorsal cervical scoliosis, with the convexity to the right. Flexion and extension of the neck was good. The pain was marked in the midportion of the left side of the neck. The head could be bent to a 30° angle with the shoulder on the right and to a 55° angle on the left, and could be rotated 80° to the right and 60° to the left. There was tenderness along the left trapezius ridge, which was most marked in the region of a firm nonmovable mass that seemed to arise from the deep structures of the neck at the level of the transverse processes of the fourth and fifth cervical vertebrae. No pulsations were felt. There was hyperesthesia along the lateral aspect of the left arm and over the left shoulder. No loss of temperature, touch or vibration sense could be elicited. The left biceps and radial periosteal reflexes were absent. The plan-

tar responses were equivocally positive. Both hands perspired profusely. The pupils were equal and round. The diaphragm was percussed lower on the right than on the left. Examination of the

FIGURE 1.

heart, lungs and abdomen was negative, as was a pelvic examination.

The blood pressure was 104 systolic, 70 diastolic. The temperature was 98°F., the pulse 70 and the respirations 20.

Examination of the blood revealed a red-cell count of 5,300,000 with a hemoglobin of 13.6 gm. and a white-cell count of 6000 with 67 per cent polymorphonuclear leukocytes. The urine was normal. Repeated tests for the presence of Bence-Jones protein were negative. The blood Hinton test was negative. The serum calcium was 10.4 mg. per 100 cc., the phosphorus 4.0 mg., the phosphatase 2.2 Bodansky units, the protein 5.2 gm., and the albumin 3.7 gm. and the globulin 1.5 gm., giving an albumin-globulin ratio of 2.4. A spinal tap showed an initial pressure of 135 mm. of water. The dynamics of the fluid were normal, and it contained 1 lymphocyte and 14 red blood cells per cubic millimeter; the spinal-fluid protein was 29 mg. per 100 cc.

An x-ray film of the spine showed changes in the third, fourth and fifth vertebrae (Fig. 1). The articular processes and possibly the transverse processes of these three vertebrae formed one mass; the bodies and the greater part of the laminae and

spinous processes were destroyed by what seemed to be an expansile growth. An anteroposterior view of the lumbar spine showed no abnormalities. A chest plate was negative.

An operation was performed on the twenty-second hospital day.

DIFFERENTIAL DIAGNOSIS

DR W. JASON MIXTER: From the history we find a patient who had a lesion in the neck characterized by stiffness, by localized swelling and by pain, both locally and running down into the shoulder and the arm. The neck is a beautiful grab bag for almost any pathologic process, almost but perhaps not quite so good as the lower lumbar spine and sacrum. So far, however, there is little of diagnostic value. Although pain is usually absent in benign tumors of bone, this does not hold in cases involving the spine.

DR CHARLES C. SIMMONS: No, this is not bone pain but is caused by pressure on nerves.

DR MIXTER: Yes. Since the pain is due to nerve pressure, we cannot consider that pain is a diagnostic sign. Therefore, from the history alone we gather nothing except that the patient had a mass in the neck causing compression of the cervical plexus. Therefore, local examination simply confirms the impression that she had a tumor in its widest sense, in the cervical region. The fact that she could move her neck as well as she could tends to rule out an inflammatory condition or a malignant tumor, although not entirely. At any rate she had a tumor approximately at the level of the transverse processes of the fourth and fifth cervical vertebrae, with some loss of function in the arm.

The neurologic examination was not helpful. It suggests nerve compression. The plantar reflexes were equivocally positive. That is somewhat suggestive because then we begin to wonder whether she had spinal cord compression as well as compression of the nerve roots leaving the spine in the cervical region. Nothing is said about the knee jerks and ankle jerks or about clonus. I presume they were negative and absent, respectively.

DR TRACY B. MALLORY: I think it is safe to assume they were.

DR MIXTER: Repeated tests for Bence Jones protein were negative. At the same time we know that the absence of Bence Jones protein does not rule out the characteristic lesion that causes it. However, the serum calcium and various other blood constituents were normal so we come down to the lumbar puncture. We can probably rule out an inflammatory lesion on the basis of the spinal fluid findings, and I believe that the serum pro-

tein and other blood chemical findings rule out a widespread bone lesion.

The spinal fluid findings point away from compression of the spinal cord itself. The presence of one lymphocyte and fourteen red blood cells per cubic millimeter is unimportant and probably represents a slightly bloody tap. Therefore we can rule out an inflammatory lesion, probably including tuberculosis, and we come back to neoplasm.

The history suggests that it was of considerable duration because we find that for several years she had had brief attacks of stiff neck that had spontaneously cleared up. During the few months before entry, progression of the disease had been a good deal more rapid. So we come to the x-ray examination, which is of great value in lesions of the cervical spine.

DR RICHARD SCHATZKI: The record adequately describes the lesion. I do not see anything to add except that the process has led to marked shortening of the cervical spine.

DR MIXTER: Can you tell me which is the first dorsal vertebra?

DR SCHATZKI: Here is the first rib, this is the first dorsal vertebra.

DR MIXTER: In other words, the first, second, sixth and seventh vertebrae were normal. Hence, the lesion includes three vertebrae. Three vertebral bodies were thrown into one, with the spinous processes of the third and fourth fused together. There was certainly fusion of the spinous processes which points to a malformation, probably congenital. All that suggests that it had been going on a long time. There was a tumor on the left side of the neck, and the right side also appears to be involved.

We come down then to a lesion involving the bodies, the laminae and the spinous processes of three vertebrae. A lesion of that sort certainly suggests extremely slow growth and a congenital lesion, because that amount of fusion in the spinous processes usually occurs only in congenital lesions. We must also remember that the patient had a congenital anomaly of one foot. However, since the lesion increased rather rapidly during the years of early adult life, we cannot put it down as a purely congenital lesion of bone. Something else occurred that produced swelling and increasing pressure on the nerve roots. The lesions that I should think of in this connection are chordoma, giant-cell tumor and an enchondroma. There may be a good many others, but these three are the likeliest. I will put chordoma first.

DR MALLORY: Dr Schatzki, will you tell us how the argument ran in the X-ray Department?

DR SCHATZKI: I remember the case well and I believe that we said it was impossible to explain the whole thing by one lesion. The patient must have

had a congenital anomaly to account for the fusion of the three vertebrae, but that did not explain the expansile growth that the patient obviously had. The conclusion as I remember it was that she had two things, a congenital anomaly and an expansile growth; I believe we put giant-cell tumor first.

DR. MALLORY: Dr. Simmons, have you any comment?

DR. SIMMONS: I think Dr. Mixer has covered the situation well. My first thought would be a congenital anomaly because primary bone tumor rarely involves three adjacent bones. Destructive primary bone tumors have occurred in a few vertebrae, the commonest being the giant-cell tumor. I do not see how you can prove a chordoma. They usually occur at the extreme ends of the vertebral column.

DR. MALLORY: This is a possible situation for chordoma.

DR. SCHATZKI: Does it grow into the transverse processes?

DR. MIXER: I do not know that it does. I think that it could because one can see it growing into the bone at the base of the skull and out into the sides of the sacrum. There is no reason why it should not go out into the transverse processes. With all this destruction it may well be that your guess is better than mine; in other words, it may have been a giant-cell tumor.

DR. SIMMONS: In this hospital there have been several cases of giant-cell tumor in that situation.

DR. MIXER: To have congenital anomaly—I think all three of us are in agreement on that—and a neoplasm on top of it is an interesting combination.

CLINICAL DIAGNOSIS

Benign giant-cell tumor.

DR. MIXER'S DIAGNOSES

Congenital anomaly of cervical spine.

Chordoma?

Giant-cell tumor?

ANATOMICAL DIAGNOSIS

Benign giant-cell tumor.

PATHOLOGICAL DISCUSSION

DR. MALLORY: It was argued on the wards that one must assume both a congenital anomaly and a neoplastic process. For the latter, chordoma and benign giant-cell tumor were most generally considered.

The lesion was biopsied and showed giant-cell tumor. Subsequent to the biopsy a great deal of argument developed about whether the patient

should be treated by radiation, surgery or a combination of the two. The final consensus was to try radiation, which has been given in three courses with a considerable degree of improvement. The tumor mass has decreased significantly in size and the nerve-root pain seems to have disappeared entirely. On the other hand, the patient is not cured as yet; she is still coming back for treatment.

DR. MIXER: Since it was a giant-cell tumor I should like to ask Dr. Simmons how he would feel in a case of this sort about getting out as much of the tumor as possible and packing the tumor cavity with bone chips.

DR. SIMMONS: Following radiation a giant-cell tumor may be destroyed, but new bone is rarely laid down. The cavity is usually filled with fibrous tissue. The few cases that I have seen in which bone chips have been introduced have not formed new bone successfully. That is not true in an ordinary bone cyst.

CASE 29112

PRESENTATION OF CASE

First admission. A fifty-two-year-old single, former fisherman entered the hospital because of persistent burning epigastric pain.

Approximately twenty-five years before admission the patient began to suffer with occasional attacks of persistent burning epigastric pain, which was usually relieved by soda or food. These attacks occurred many times each year and lasted about a week but never interfered with his daily activities. Occasionally during an attack he belched a great deal, but he did not vomit. Seven years before entry, following the death of his mother, he was forced to live alone. Since then the attacks had occurred more often. A year before admission the pain became severer, and the patient gradually lost a great deal of weight and felt weak. He was seen in the Out Patient Department. At that time a healed, nonobstructing duodenal ulcer was demonstrated by x-ray studies. Ulcer diets partially relieved the discomfort, but the patient failed to gain weight.

The family history was noncontributory.

When thirty-two years old the patient had a sore on the glans penis, which healed promptly following topical treatment. Six years later both lower legs were amputated at the calf because of gangrene of the feet following frostbite.

Physical examination disclosed a markedly emaciated man who was nothing more than "skin and bones." However, he appeared to be comfortable. Examination of the heart, lungs and abdomen was negative.

The blood pressure was 88 systolic, 64 diastolic.

The examination of the blood revealed a red-cell count of 5,290,000 with a hemoglobin of 90 per cent, and a white-cell count of 7400 with 82 per cent polymorphonuclear leukocytes. The urine was normal. The blood Hinton test was negative. A stool was guaiac negative. A barium meal demonstrated a characteristic clover-leaf deformity in the duodenal cap but no crater was visible; the pylorus opened readily. A barium enema was negative.

The patient improved and gained weight on a high-vitamin, high-calory diet with supplementary iron, and was discharged on the thirty-third hospital day.

Final admission (six years later). The patient was readmitted because of sharp, crampy abdominal pain and constipation.

Following discharge the patient again suffered with epigastric burning pain, weakness and weight loss despite an adequate diet and rest in a convalescent home. Three and a half years later he began to worry about "people talking about him," and his abdominal pain seemed worse. Occasionally he became bloated and had slight heartburn when he ate small amounts of food. He never became distended and did not belch, but passed large amounts of flatus, which seemed to relieve him. Six months later a barium meal demonstrated that the duodenal cap was grossly deformed and that there was a shallow ulcer crater posteriorly; there was also some associated spasm of the first portion of the duodenum. The remainder of the examination was negative, as was a barium enema. The patient was treated with tincture of belladonna and a six-meal-a-day diet and seemed to improve. A gastrointestinal series four months later showed no definite evidence of activity in the crater of the duodenum.

Four days before entry he began to suffer with rather severe generalized abdominal cramps, which were most marked in the upper quadrants and were not relieved by food. These continued to the time of admission. He did not feel nauseated and did not vomit. Since the onset he had not moved his bowels or passed any gas, despite a desire to do both.

Physical examination revealed a mildly disoriented man. Examination of the heart and lungs was negative. The abdomen was moderately distended. There were generalized tenderness and spasm, but these were most marked over the lower abdomen. One observer demonstrated shifting dullness in the flank. The rectum was filled with firm impacted feces. The prostate was twice its

normal size, and was moderately tender and firm. No pelvic masses were felt, and no areas of tenderness were elicited.

The blood pressure was 72 systolic and 40 diastolic.

The red-cell count was 3,350,000, and the white-cell count 3500. The urine showed a +++ test for albumin.

A flat x-ray film of the abdomen showed marked dilatation of the sigmoid and a ground-glass appearance suggestive of free fluid. A small amount of barium inserted through the rectum passed to the rectosigmoid, where it appeared to be blocked; it was difficult to be certain of this, however, because the patient's relaxed anal sphincter permitted spilling of the barium.

Despite the administration of infusions of physiologic salt solution and glucose, blood transfusion and oxygen, the patient failed rapidly and died approximately sixteen hours after admission.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD B. BENEDICT: This is a fairly obvious history of duodenal ulcer,—epigastric pain relieved by food,—and x-ray examinations on several occasions confirmed the diagnosis.

The sore on the glans penis is probably of no importance. It healed promptly, and later a Hinton test was negative. I cannot relate that to the gastrointestinal story.

The fact that he was down to "skin and bones" on the first admission makes one think of carcinoma, but since he recovered so rapidly and since his red-cell count was normal, such a diagnosis seems unlikely. Furthermore the patient was alive six years later.

Barium enemas were done several times and were consistently negative until the last admission, which may be of some significance.

The interesting part of the story is the acute episode that began four days before the final admission. The symptoms were then characterized by severe generalized cramps, mostly in the upper quadrants, and the patient had not moved his bowels or passed any gas. The question is whether he had a large-bowel obstruction with perforation or a perforated duodenal ulcer. Against a perforated duodenal ulcer is the fact that he had no sudden pain, as one would expect with a perforated ulcer, and there is no mention of any air under the diaphragm in the flat plate. He had an anemia, which would not be explained by a perforated ulcer, and a barium enema would probably not have been given if his attending physicians had thought the lesion was an acute perforated ulcer. The anemia certainly goes with a carcinoma of the sigmoid, and the x-ray findings were consistent with

a perforated carcinoma of the sigmoid. The white-cell count was low and cannot be explained by perforation unless the patient had an overwhelming infection, with no white-cell response. The temperature, pulse and respirations are not given.

From what I have read so far I am inclined to diagnose a duodenal ulcer and, in addition, a perforated carcinoma of the sigmoid. Will you show the x-ray films, Dr. Holmes?

DR. GEORGE W. HOLMES: Most of the x-ray films were taken at previous admissions. There is only one film taken at the last admission, and I am afraid that it is not going to help us. Apparently no film was taken at the time he spilled the enema. The films taken two years before the final admission were interpreted as negative, and I see no good reason to think differently. The only possibility is in the region of the cecum, but there is a good mucosal pattern all the way through and I am inclined to agree with the report. Of course there was plenty of time for something to have happened in the interval. In the last film there is a loop of dilated bowel on the left side, which appears to be large bowel. The bowel above it looks as if it contained fecal material. In other words, there is evidence of obstruction rather low in the large bowel, and nothing more.

DR. BENEDICT: How much weight do you put on the fact that the patient expelled an enema?

DR. HOLMES: If he had obstruction low down and was rather sick that is not an uncommon happening.

DR. BENEDICT: You think that he probably had obstruction?

DR. HOLMES: Yes. The only other explanation is that he was too sick to pay attention to what was going on.

DR. BENEDICT: I shall stick to my diagnosis.

DR. TRACY B. MALLORY: In view of the profound malnutrition, I doubt that the anemia was significant.

A PHYSICIAN: Was there any spinal-fluid test to rule out neurosyphilis?

DR. MALLORY: No. The opinion of the service was approximately that of Dr. Benedict. It was believed that the patient had large-bowel obstruction and that the duodenal ulcer was inactive.

CLINICAL DIAGNOSES

Volvulus of sigmoid, with perforation and peritonitis.

Perforated duodenal ulcer?

DR. BENEDICT'S DIAGNOSES

Duodenal ulcer.

Carcinoma of sigmoid, with perforation.

Peritonitis, general.

ANATOMICAL DIAGNOSES

Duodenal ulcer, with perforation.

Peritonitis, generalized.

Tuberculosis, healed, right apex.

Arteriosclerosis, generalized.

Amputation of both lower legs.

PATHOLOGICAL DISCUSSION

DR. MALLORY: At autopsy we found a perforation, 0.5 cm. in diameter, of the duodenum through the base of a chronic ulcer. The large bowel was obstructed, but merely by fecal impaction, which was of impressive extent. There was, of course, a generalized peritonitis. Nothing else of significance was found. There was no evidence that he had ever had syphilis.

AMERICAN RED CROSS

ALTHOUGH the collection of the blood for the 4,000,000 pints of plasma requested by the Army and Navy from the American Red Cross in 1943 is an undertaking whose difficulty and cost are readily appreciated not only by physicians but by the lay, this is merely one of the many useful and necessary functions related to the war effort that are being carried on by this organization. And of these functions, Home Service is an activity concerning which little is known.

Red Cross Home Service has been maintained for many years, and under peacetime conditions is an important cog in the machinery of disaster relief. Recent examples of this work in New

England include the aid given—and still being given—to families rendered destitute by the hurricane of 1938 and the care and help provided for persons involved in the Coconut Grove fire in Boston and for their families.

With the advent of war, the responsibilities of Home Service have increased manyfold. This is clearly evidenced by the fact that the personnel of this department of the Boston Metropolitan Chapter has increased from four in 1941 to one hundred and seventy five in 1943, with a corresponding increase in monthly budget from \$150 to \$6000. All this has been occasioned by various services to men in the armed forces—activities that are acknowledged by the Army and Navy to increase the fighting fitness of soldiers and sailors. The work, which is largely a co-operative effort of the Red Cross field service men at camps and at the front and the Home Service divisions at home, includes the following accurate information for the man who is worried about conditions in his home; the investigation of requests for emergency fur-
lough, with financial aid, if necessary, care for and assistance to the families of soldiers and sailors who have been killed or reported missing, and aid to former service men or their families in the filing of claims for relief funds or pensions.

This is part of the reason why the American Red Cross must raise \$125,000,000. It is part of the reason why the Boston Metropolitan Chapter must raise \$2,145,000, and why the suburban chapters must raise \$860,500 more. Surely no one can question the need for such a large sum of money, even though the drive comes at a time when the budgets of most families are in a precarious position. The men in the armed forces deserve all this, and more.

NATIONAL HEALTH ADVISORY COUNCIL

MOVEMENTS to improve the national health are numerous and familiar. But it cannot be expected that the health situation of the people will be per-

a perforated carcinoma of the sigmoid. The white-cell count was low and cannot be explained by perforation unless the patient had an overwhelming infection, with no white-cell response. The temperature, pulse and respirations are not given.

From what I have read so far I am inclined to diagnose a duodenal ulcer and, in addition, a perforated carcinoma of the sigmoid. Will you show the x-ray films, Dr. Holmes?

DR. GEORGE W. HOLMES: Most of the x-ray films were taken at previous admissions. There is only one film taken at the last admission, and I am afraid that it is not going to help us. Apparently no film was taken at the time he spilled the enema. The films taken two years before the final admission were interpreted as negative, and I see no good reason to think differently. the senior gas officers of defense councils in the organization of state and local programs. The senior gas officer trains gas reconnaissance agents who serve in the respective zones of their city. These men are responsible for the identification of the agent, the collection of samples, the prevention of casualties and the delimiting of gassed areas, and also for co-operation with Emergency Medical Service, the health department and other agencies concerned in protection against gas.

For Emergency Medical Service the duties are set forth as follows:

Duties before gas attack

- 1 Plan, with the assistance of the senior gas officer for the establishment of stations for the cleansing of gassed patients with other injuries and for the cleansing of civilian protection personnel. Each hospital of 150 beds or more should be provided with a cleansing station. Cleansing stations should be available in the ratio of one per 50,000 population and should be located at small hospitals or casualty stations if 150 bed hospitals are not available in this ratio.
- 2 Recruit, train and assign personnel to gas-cleansing stations for cleansing services.
- 3 Provide instruction, in co-operation with the senior gas officer, for general public and civilian protection personnel in self-protection and self-cleansing.
- 4 Provide for instruction of physicians in diagnosis and treatment of chemical casualties.
- 5 Assist hospitals in planning for the handling of gas casualties.
- 6 Assure adequate distribution of protective clothing and gas masks and other protective equipment to members of mobile medical teams and train personnel in their use.
- 7 Make provision for training drivers of ambulances and sitting-cars in the protection of their equipment against liquid gas contamination, inform them of arrangements for vehicle decontamination by Emergency Public Works Service.
- 8 Arrange for the protection from contamination of the equipment used to transport contaminated casualties in so far as it is possible.

Duties during gas attack

- 1 On advice of the senior gas officer and under the orders of the commander, man the gas cleansing stations.
- 2 Advise other services of the Office of Civilian Defense in regard to first aid cleansing of their personnel.
- 3 Assign a mobile medical team to gas cleansing stations for first aid.

Duties after gas attack

- 1 Evaluate the effectiveness of the cleansing procedures that have been used.
- 2 Provide follow up treatment of patients.
- 3 Prepare an inventory of protective equipment available for use in future attacks and obtain additional equipment as necessary.
- 4 Cleanse bodies of the dead to facilitate identification.

Gas masks are now being distributed to the personnel of the protective services.

Masks should be kept at the post where the protective personnel will assemble during drills or enemy action, not carried by them during their daily activities. It is recommended also that about 20 per cent of the masks allocated to each service be stored as a reserve. It is important that the reserves be decentralized as a safeguard against destruction by fire or bombing and also to permit rapid distribution in case of an emergency.

Since valuable and critical materials are used in the manufacture of gas masks, the utmost care must be exercised in their handling, distribution and storage. No person should receive a mask until he has been trained in its use and care, including proper storage.

Storage must be in a cool dry place, and masks should be kept from contact with sunlight, oils and corrosive liquids and vapors. After use, masks should not be worn by another individual without proper sterilization.

Repair of masks is not to be attempted locally except in case of extreme necessity. Broken and defective masks or those with exhausted canisters should be collected by the local property officer and returned to the supply depot for repair and replacement.

MISCELLANY

ARMY NAVY AWARD

TO PARKE, DAVIS AND COMPANY

The Army Navy pennant for excellence in production was awarded to Parke, Davis and Company, of Detroit on February 26. Brigadier General John M. Willis, commanding officer at Camp Grant, Illinois, presented the award which was received by Dr. A. W. Lescohier, president of the company. The insignia, which all employees are entitled to wear, were presented by Lieutenant J. B. Williams, senior medical officer of the Detroit Naval Armory, and were accepted by John Tighe, representing the employees.

NOTES

Dr. Ralph E. Wheeler, assistant professor of public health at Vanderbilt University, has been appointed professor of bacteriology at Tufts College Medical School. Dr. Wheeler graduated from Harvard Medical School in 1930 and received the degree of Doctor of Public Health from Johns Hopkins University in 1932. He will assume his new duties on April 1.

BOOK REVIEWS

Serology in Syphilis Control: Principles of sensitivity and specificity. By Reuben L. Kahn, M.S., D.Sc. 8°, cloth, 206 pp., with 35 tables and 1 chart. Baltimore: The Williams & Wilkins Company, 1942. \$3.00.

Hinton, Kahn and Kline have worked out precipitation tests in syphilis that are used on a large scale as supplements to or substitutes for the Wassermann reaction. These tests are being applied to millions. It is regrettable that quantitative procedures, such as Kahn discusses in one of the chapters of this monograph, have not had sufficient trial in practice, Wassermann, recognizing their importance, studied this problem for years. This book, however, does not deal primarily with the technique, but with the development, establishment and maintenance of sen-

sitivity and specificity levels of the tests, with special reference to the control of syphilis.

The role and limits of these tests are discussed in detail in the first four of the fourteen chapters; and their source is traced to the discoveries of the phenomena of complement fixation and precipitation in a survey that will be of interest to the historian of immunology. Although citing Neisser and Sachs as starters of the application of the Bordet-Gengou reaction to syphilis in his historical sketch occupying two chapters, the author does not quote the inspiring influence of Moreschi's phenomenon on their researches. A formula that takes into account the two main factors affecting the diagnostic value of serologic tests is the leitmotiv of the following chapters, in which the use of the supersensitive (presumptive) as well as of multiple tests is authoritatively discussed. The importance of standardization and the need of co-operation by syphilologists in carrying out this task are emphasized in a separate chapter. The first of the two chapters forming an appendix gives useful directions concerning the value of serologic tests for the control of syphilis by public-health officers. The summaries of fifteen papers presented at two conferences held in Ann Arbor bring to a close this interesting monograph.

The aim to give a fuller understanding of the principles of serology underlying the tests, without debating which one is the better or the poorer, has been properly achieved. The considerations brought forth by the author will enable the physician to best utilize these tests in the diagnosis and treatment, as well as in the control, of syphilis.

Intestinal Obstructions: A physiological and clinical consideration with emphasis on therapy. By Owen H. Wangenstein, M.D., Ph.D. Second edition. 4°, cloth, 484 pp., with 143 illustrations and 44 tables. Springfield, Illinois: Charles C Thomas, 1942. \$7.00.

It is only during the past decade that the complicated problems of intestinal obstruction have been attacked vigorously by the experimental method. No one figure stands out more prominently in the advances of this era than that of Wangenstein. Not only has he labored in the clinic and laboratory to find the answers to many of the unknowns of intestinal obstruction, but he has stimulated others to search for answers.

This book is a scholarly summary of the knowledge of intestinal obstruction to date. Many have associated the name of the author with the conservative treatment of intestinal obstruction. This is but a half-truth, and one need not read far into the book to discover that Wangenstein also operates for intestinal obstruction. The heading of one chapter is "Surgery: The mainstay of therapy." Cases of simple obstruction without strangulation can be safely treated by duodenal suction and the finesse of the surgeon lies in his ability to diagnose simple obstruction. Even Wangenstein seems to err on the side of operation when there is doubt of strangulation, but in the majority of cases he believes that a differentiation can be made on the basis of clinical and laboratory findings. The main thesis of the book, however, is not whether to operate. In spite of the author's personal experiences in this respect, he has risen above things close at hand and has given as impartial and comprehensive a review of intestinal obstruction as seems possible at the moment.

The physiology and pathology of intestinal obstruction are discussed in detail. At the end of the chapter "Effects of Distention," the author concludes that mechanical factors are far more significant than toxic factors in

explaining the effects of low intestinal obstruction. This essential clarification of a complex problem by a thorough rationalization of experimental data provides an eminently sound basis for all the therapeutic procedures that follow. The use of suction and its indications are reviewed. The surgical treatment of specific obstructions, such as intussusception, paralytic ileus and colonic obstruction, is given, with excellent drawings showing technic and pictures of illustrative cases. A lengthy bibliography follows each chapter.

Certain repetitions in the work are noticeable even when one reads through hurriedly. However, these are necessary to make a fairly complete unit of each chapter without resort to cross-reference. This feature makes the book a handy and readily available guide when specific problems concerning intestinal obstruction arise.

Psychotherapy in Medical Practice. By Maurice Levine, M.D. 8°, cloth, 320 pp. New York: The Macmillan Company, 1942. \$3.50.

This book gives in detail the various types of psychotherapy that can be applied in the treatment of the mental states, particularly the neuroses. The writer is a psychoanalyst and believes this is the best approach to the treatment of mental disorders. He does not, however, deny the limited value of the other forms of psychotherapy.

From the standpoint of the exposition of technic and the details of approach to patients, his book can be recommended as a useful addition to the general practitioner's library. From other standpoints, however, the reviewer finds much to criticize.

The familiar position of psychoanalysts — that they understand and can cure most of the mental difficulties of mankind — is well exemplified by the author. The psychiatrist knows all about the bringing-up of children, as well as being competent to advise in matters of marriage, sex, social relation, the choosing of a career and so forth, and the book provides a ready answer for difficulties, maladjustments and those mental illnesses concerning which psychiatry is, in reality, in a state of incomplete knowledge, to put the situation mildly. For example, the neuroses are not as yet understood either regarding genesis or regarding treatment, these fundamentals being quite unsatisfactory despite the claim of the psychoanalysts. Certainly the psychiatrist qua psychiatrist has not the wisdom, let alone the knowledge, to advise the human being successfully, beset as he is by the incongruities, cruelties and crudities of modern social structure, nor is there yet any ready reconciliation of the opposing forces to which every human being is subjected from the cradle to the grave. Psychotherapy of whatever form must yet prove its claims in the treatment of the major neuroses. It has contributed nothing of importance to the treatment of the psychoses, and it has remained for the physical approaches, such as shock treatment, to make an inroad on the grave problems presented by schizophrenia and manic-depressive psychosis. It seems safe to say that more concrete knowledge is to be expected from brain-wave studies than from any psychologic analysis yet evolved.

In the reviewer's opinion, extraordinary claims on the part of psychiatrists injure the growth and development of one of the most important and slowly developing branches of medicine. The psychiatrist has two main duties — to be humble in his claims and industrious in his researches.

NUMBER 12

THE BLOOD PRESSURE OF ADOLESCENTS Observations on Two Hundred and Twenty Students

HOMER E. LAWRENCE, M.D.*

BETHEL, MAINE

DURING the routine annual examination of 220 healthy male and female adolescent students, I was impressed with the frequency with which the blood-pressure readings reached elevated levels. In many cases, rapid pulse, excessive perspiration, vasomotor phenomena and other signs of excitement were absent. It was therefore decided to make further observations on these subjects, to compare the incidence of abnormal pressures with that in a group of young adults and, where possible, to obtain information regarding the blood pressures of the parents.

NORMAL BLOOD PRESSURES OF ADOLESCENTS

Before classifying a given blood-pressure reading as abnormal, it is necessary to know the normal reading for persons of the same sex and age. The blood pressure of adolescents should not be judged by adult standards. It has been pointed out that the blood pressures of normal children of the same age vary within wide limits, and that the normal value may be best described as a range.¹

The only studies of the blood pressure of sizable numbers of children available to me are those of Richey,¹ Faber and James,² Schnurman³ and Sundal.⁴ Sundal recorded only the systolic pressures obtained by the method of palpation. Schnurman did not observe persons below the age of seventeen. Faber and James did not record readings on adolescents older than sixteen. Consequently, the values given by Richey are the only ones suitable for the purpose of this study. The mean pressures and standard deviations recorded by him on students of the same age and racial stock as those observed in this study are given in Table 1.

In order to determine whether a given blood-pressure reading is normal, use is made of the statistical method of frequency distribution. This

method is explained by Faber and James² as follows. the nearer the pressure of a given subject is

to the average of all normal persons, the greater is the chance that his pressure is normal; and the greater the deviation from the average, the greater the chance that his pressure is abnormal. The proportions are determined in the statistical system by the use of a measure of deviation from the mean, or average, which is known as the "standard deviation" (the square root of the arithmetical mean of the squares of the deviations from the average of the distribution). By dividing the deviation of a given measurement from the average by the standard deviation, one obtains a quotient, called by Faber and James the "deviation index." This index is of clinical value in determining the significance of individual variations

METHOD OF STUDY

The blood pressure of each student was taken at the time of his or her annual examination, a single reading being recorded. These readings were compared with Richey's¹ statistics for adoles-

*School physician Gould Academy

cents of the same sex and age. All subjects whose deviation indices were $+2.00$ or more were recalled for a second examination. This dividing deviation indices remained $+2.00$ or above, still further readings were made, including cold-pressor tests. In addition, information regarding the in-

*These figures indicate the lowest and highest values recorded in three or more observations some days or weeks apart; the readings are given in nearest even numbers.

line is purely arbitrary; so are the criteria for classifying adult pressures as normal or otherwise. It should be noted that a deviation index of $+2.00$ indicates that the odds against that reading's being normal are 1 to 43.² In a series of ideally distributed normal cases only 2.3 per cent will have indices of $+2.00$ or higher.

Blood-pressure readings were made by a standard method⁵ by one or both of two observers, whose readings were found in preliminary tests to check closely. Beginning with this second observation, the average of three or more readings was taken as the true reading. On the students whose

cidence of elevated blood pressure in the parents was sought.

RESULTS

Of the 220 students initially examined, 82, or 37 per cent, exhibited blood pressures whose deviation indices were $+2.00$ or more. Obviously, many of the elevated readings were due to excitement, although only 13 of the 82 subjects exhibited pulse rates of 90 or above. This was made further apparent by the second observation, when only 21, or 9.5 per cent of the entire series, continued to have elevations in blood pressure of this degree.

All the subjects had high systolic levels on more than one occasion. Cases 1, 9 and 14 had elevated diastolic levels as well. There is evidence that diastolic elevations are more significant than systolic.

The cold-pressor test was done on each of these 21 subjects according to the technic described by Hines.⁶ The subject was placed at rest in a reclining position in a quiet room, and the blood pressure was taken every ten minutes until a basal level was reached. The hand was then placed in ice water up to the wrist, and the blood pressure was read on the opposite arm after thirty seconds and after sixty seconds. The hand was then removed from the water, and readings were taken every minute until the basal level was regained. An abnormal response, according to Hines, consists of an elevation of 20 mm. or more in the systolic reading, an elevation of 15 mm. or more in the diastolic reading or failure to return to the basal level within two minutes. The diastolic response is said to be a more reliable index of vasoconstriction than the systolic. Among this group there were no students with excessive systolic responses. However, 16 of the 21 subjects, or 73 per cent of the entire series, showed diastolic responses of 15 mm. or more; and 10 of the 16 showed delay in returning to the basal level. This incidence of abnormal reactions should be compared with the 18.7 per cent incidence of hyper-reactors found by Hines⁷ among 400 school children.

BLOOD PRESSURES OF PARENTS

In 11 of the families of the 21 students with abnormally high pressures, the blood pressures of one or both parents were measured by me. In 5 couples, one parent had a systolic pressure greater than 150; and in 2 others, the systolic pressures were 142 and 148 in one of the parents. Furthermore, the husband of a hypertensive mother had died of hypertension. Unfortunately, it was impossible to observe any parent on more than one occasion.

The parents of 9 students gave what information they had by letter. One father had died of the complications of hypertension; the father of another was said to be a hypertensive invalid; and the father of still another had a "slightly high" blood pressure. There was no known hypertension in the remaining 6 couples.

Thus, in 20 couples concerning whom information was available, hypertension is known to be or to have been present in 7, and possibly in 10.

COMMENT

The incidence of hypertension among Selective Service registrants is said to be 3.02 per cent.⁸

Yet in the present study, the blood pressures of 21 of 220 adolescents, or 9.5 per cent, after repeated examinations were not considered normal. This may be explained in three ways: first, because Selective Service examiners do not determine abnormality by the method of frequency distribution, as was done in this group; secondly, because at least some examiners for the Selective Service System have subjects lie down if the initial reading is elevated, thus getting something comparable to the basal level of the cold-pressor test; and thirdly, because adolescents go through a period when they have elevated pressures that may become normal in young adult life, only to rise again to hypertensive levels in middle age.⁹

The hereditary aspects of hypertension have been pointed out repeatedly,^{7, 10-12} so that no comment on this aspect of the present study is needed here.

CONCLUSIONS

The drawing of definite conclusions regarding blood pressure from such a small number of observations is not in order. However, the following statements seem justified:

Blood-pressure determination should be part of the examination of students, but only if the readings can be checked at one or more later dates, for the pressures of adolescents are labile.

A certain proportion of students—9.5 per cent in this group—will show abnormally high pressures, as determined by the method of frequency distribution, after repeated observations. Most of these persons come from hypertensive families.

The frequency of abnormal pressor tests among these adolescents with abnormal pressures tends to confirm the impression that many of them are in a prehypertensive stage.

There is need for follow-up of subjects such as those described, in order to determine in later years whether elevated blood pressures and abnormal pressor tests during adolescence are truly indicative of a prehypertensive state.

THE USE OF COAL TAR IN THE TREATMENT OF SKIN DISEASES*

FRANK C. COMBES, M.D.†

NEW YORK CITY

IN THE field of dermatology there probably exists no more valuable and useful remedy than crude coal tar. Nevertheless, no other substance in the *National Formulary* varies so in composition and consequently in pharmacologic action. This physical and chemical difference of coal tars derived from varied sources was originally emphasized by Dind,¹ who compared coal tars obtained from the gasworks of Lausanne, Geneva, Zurich and Basle. Brocq² recommended that one should insist on obtaining the coal tar produced in the making of illuminating gas. In these times it is impractical if not impossible to pursue such a policy. Many dermatologists when prescribing coal tar refer the patient to a certain pharmacist because the former knows the type of coal tar dispensed. If this is not practical, experience has shown that the patient not infrequently is given a mixture of uncertain composition, poorly compounded, which not only fails to benefit him but may be actually injurious. Furthermore, it is astonishing how often, when one prescribes *pix carbonis*, the pharmacist dispenses *liquor carbonis detergens*, a 20 per cent solution in an alcoholic soap-bark vehicle.

At the present day not only do the available coal tars differ from each other, but they all differ materially from that formerly recommended by Brocq, Jambon, Dind, Jadassohn and other European dermatologists. White,³ who introduced the use of coal tar in this country, was the first American dermatologist to mention this difference. Schamberg⁴ was so impressed with the unsatisfactory action and variability of the substance that he imported European tar for the use of his patients.

For a number of years at Bellevue Hospital, our experience has been similar to that in other sections of the country. Various lots of coal tar have differed in physical characteristics, color, consistence, homogeneity and therapeutic effect. On some occasions the substance used has been actually irri-

tating. This difference is due not only to the crude tar itself but also to the method by which the paste is compounded. It is extremely difficult to prepare by hand a good paste in large quantities. The finished product should be smooth, homogeneous and almost black. This shade does not differ perceptibly in pastes containing from 3 to 10 per cent of crude tar. Inferior and unsatisfactory pastes are sometimes an olive green, often flecked with small black particles, and lack the characteristic naphthalene-like, gassy odor.

What are the reasons for these differences in coal tars from different sources? The coal tar used by the early European dermatologists was the residue from anthracite coal in the manufacture of illuminating gas (*pix lithanthracis*). There were few uses for the crude tar, other than as a paint for wood, iron, rope, roofing, brickwork or stone as a protection against weather and fungi. It was subsequently distilled solely for the purpose of obtaining naphtha, creosote and phenol. In more recent years the value of coal-tar distillation fractions has assumed such importance in the arts and in industry that the manufacture of illuminating gas must be considered secondary. The separation of its constituents became an industry much more important than all the applications of crude coal tar itself. It was found that with variation in the temperature of the coal ovens, the time of distillation, the type of oven (vertical or horizontal) and so forth, differences occurred in the type of tar produced; that is, certain fractions were increased or decreased in amount. Coal tar was subsequently produced, therefore, of a composition depending on what fraction was particularly desired. This explains in part why many manufacturers use petroleum oil, coke, splint coal, lignite and other carbonaceous material, although the tar is medically more valuable when materials other than real coal have been used.

The only solution to the coal-tar problem appeared to be that a good crude product should be obtained and a competent manufacturer desig-

*From the Department of Dermatology, New York University College of Medicine, and the Dermatological Service of the Third (New York University) Medical Division, Bellevue Hospital.

†Professor of dermatology and syphilology, New York University College of Medicine; director of dermatology and syphilology, Bellevue Hospital.

nated to prepare a good paste. This was done, the product* consisting of the following ingredients:

Crude coal tar	2.88
Zinc oxide	5.37
Starch	53.75
Petrolatum, q. s. ad	100.00

METHOD OF APPLICATION

Detailed attention to the correct method of application and removal of coal-tar paste is essential to the best results.

All previous medication should be carefully removed by means of some fixed oil. The paste should then be applied directly by means of a wooden spatula in a layer just thick enough to cover the lesion. The entire area should then be dusted with talcum until the surface is white. If possible it is preferable not to cover the lesion with a dressing. If this cannot be avoided, the lightest type of dressing should suffice. The paste should remain undisturbed for at least twenty-four hours, and in some cases it may be left for two or three days.

Removal is best accomplished by using mineral oil or an emollient cream. No attempt should be made to cleanse the area completely; only the loose particles should be removed. A new layer of coal-tar paste is then applied in the manner previously described.

If papules appear on the treated area, the coal tar should be discontinued. They are the forerunners of pustules which may complicate therapy and are encouraged by too much bandage and a paste that is too thin.

Tar which has soiled linens and bedclothing may be readily removed by rubbing both sides of the material with lard and washing with soap and water.

The following precautions should be observed:

Avoid exposure to direct sunlight of the area to which tar is applied or has recently been applied. Tar is a photosensitizer, owing to the presence of acridine and anthracene oils.

Avoid prolonged use of tar on hairy areas. Folliculitis may occur, owing to pitch and paraffin oils.

Avoid changing the dressing often.

Do not apply tar to infected or impetiginized lesions.

Do not apply tar to more than one quarter of the body surface at one time. There is danger of absorption, since coal tars contain from 2 to 4 per cent phenol.

Be on the lookout for evidence of sensitivity after prolonged use.

Keep coal tar and coal-tar pastes in carefully sealed containers to avoid evaporation of volatile ingredients, which constitute a valuable part of their efficiency.

PHARMACOLOGIC ACTION

Since coal tar is not a uniform entity, its therapeutic action depends on the aggregate effect of its components. As these vary both qualitatively and quantitatively there must of necessity be minor variations in clinical effects between different samples of tar.

The antiseptic and antipruritic effects depend chiefly on naphthalene and the phenols and cresols. In a dilution of 0.1 per cent, tar exerts a definite astringent action.

The predominant effect of coal tar is keratoplastic, which is dependent on the presence of methylnaphthalene, dinaphthalene, xylenol and naphthol. Sulfur, which is present in a concentration of approximately 0.2 per cent, may contribute slightly to the keratoplastic action.

The reducing action of coal tar is closely related to its keratoplastic effect, and coal tar is exceeded in this respect only by dioxyanthranol, chrysarobin, pyrogallol and juniper tar. It has one distinct advantage over these substances: it can be used on vesicular lesions, which are invariably irritated by the other potent reducing agents.

The ability of coal tar to penetrate the epidermis depends on the presence of distillation products with high boiling points, especially methylnaphthalene. It abstracts oxygen from the skin, thereby inhibiting mitosis and resulting in a numerical and dimensional decrease in the cells of the rete malpighian and corneous layers.

CLINICAL USE

Infantile eczema. No single topical remedy is so beneficial in this condition as a properly prepared coal-tar paste. Those cases in which the face is covered with a crusted vesicular dermatitis are particularly amenable. The paste is applied in the usual way and a mask of soft light muslin or cotton cloth, fenestrated for the nose, mouth and eyes, is used to cover it. The dressings are changed not oftener than every twenty-four hours.

Occupational dermatitis, dermatitis venenata and contact dermatitis. These three dermatoses, which have certain features in common, are invariably benefited, whether they are vesicular or lichenified. With the multiplication of factories and new industries incident to the war, occupational dermatoses assume a new importance. The causative factors may be briefly classified as follows: mechanical irritants (dusts, sand, silicates, carborundum, duralumin, steel filings and so forth); inorganic

*The coal tar paste referred to is Daxalan, manufactured by Dome Chemicals Inc., of New York City; the tar is obtained from the Barrett Company Edgewater New Jersey

chemical irritants (soaps, soda, potash, lime, ammonia, mineral acids and so forth); organic chemical irritants (coal-tar derivatives, dyes, paints, plants and so forth); and mineral oils and greases. One precaution in the treatment of dermatoses due to contact substances is to avoid coal tar if there is much edema or any secondary infection. Cold, wet compresses of Burow's solution or boric acid should be used first to prepare the involved area for the coal-tar paste. Improvement is often dramatic and may be expected within a few days.

Dermatophytosis. Fungus infections of the feet and crotch, when vesicular, and vesicular dermatophytids of the hands respond well to the application of coal tar, although it exerts no direct lethal influence on the infectious agent.

Varicose eczema. Varicose eczema and varicose ulcers are promptly, although often only temporarily, improved by coal tar. In the absence of secondary infection there is no other agent that affords such rapid improvement.

Dermatitis hiemalis. By winter dermatitis is meant a condition characterized by more or less circumscribed, nummular and discoid areas of vesiculation, occurring in the winter, especially on the lower extremities, in individuals with a sluggish peripheral circulation, and accompanied by periodic pruritus. Response to coal-tar applications is good, although at times slower than in other vesicular eruptions. If the paste is applied sparingly and well covered with talcum powder, there is little soiling of the linen. Another method is to cover a thin coating of paste with flexible collodion or latex.

Chronic exudative lichenoid and discoid dermatitis, and dermatitis exfoliativa. Pruritus and cutaneous inflammations are greatly improved by coal-tar pastes. Depending on the cause, many patients obtain only temporary symptomatic relief. In all patients with generalized or universal involvement, it is advisable to limit the application to not more than one third of the body surface at one time.

Pityriasis capitis. Although the use of coal tar on the scalp is disagreeable, when the paste is mixed with an equal quantity of a fixed vegetable oil it may be conveniently applied by means of a toothbrush. No dusting powder is used.

Pruritus ani. The response of itching in the anal and perineal regions to coal tar is erratic. When there is an associated dermatitis with fissuring, the effects are better than those in essential pruritus. If improvement is not apparent within a week, treatment should be interrupted, since in this region folliculitis not infrequently compli-

cates tar therapy. In some cases favorable results are prompt and permanent.

Chronic dermatosis. The results obtained in prurigo, lichen simplex chronicus (neurodermatitis) and atopic eczema are frequently as good as those in acute conditions, although they are slower in attainment and often only temporary.

Psoriasis. The improvement following the application of a good coal-tar paste followed by ultraviolet radiation in ambulatory patients is often as good as those following the use of chrysarobin in hospitalized patients. The method used, essentially that suggested by Goeckerman,⁵ is as follows:

Remove all scales with green soap and water previous to instituting treatment.

Apply coal-tar paste to the lesions for twenty-four hours and then remove with mineral oil until only a slight brownish stain remains.

Administer mercury-vapor quartz-lamp exposures of just sufficient intensity to avoid a reaction.

Repeat this entire procedure daily, increasing exposures to produce tanning.

Permit the patient to take a bath after each exposure before reapplying the ointment.

Favorable results are frequently apparent within three or four weeks, although, as with other methods of treating psoriasis, they are seldom permanent.

SUMMARY

Differences in various coal tars, and in addition the methods of compounding coal-tar pastes, are responsible for variations in therapeutic response of various skin diseases.

Acquaintance with the physical, chemical and pharmacologic action of a coal-tar paste is essential for the best results.

When properly used, coal tar has a beneficial effect in a large group of acute and chronic inflammatory dermatoses.

The most satisfactory results follow the use of a paste of standard manufacture.

CORNEAL TRANSPLANTATION

BRENDAN D. LEAHEY, M.D.*

LOWELL, MASSACHUSETTS

THE subject of corneal transplantation or keratoplasty has become fairly familiar to ophthalmologists in recent years, and the operation itself is being done with increasing frequency. It should be even more important in the near future in military medicine, since a large number of eyes will undoubtedly be blinded from corneal scars due to traumatic injuries with infection or to burns. Since this operation is now a well-established and fairly successful medical procedure, it appears to be of interest to the profession at large.

Transplants are classified in two ways; by surface area and by depth. According to area, they are total if the entire width of the cornea is used, and circumscribed, or partial, if only a window is taken from the cornea. According to depth, they are lamellar when only the top layers or lamellae are replaced, and penetrating when the full thickness of the cornea is transplanted. Thus one recognizes four types of keratoplasty, total lamellar, circumscribed lamellar, total penetrating and circumscribed penetrating. Only the last one has a practical significance. Lamellar keratoplasty is a conservative procedure; but since a slight layer of scar tissue forms between the new and the old lamellae, it cannot give as good a visual result as a full-thickness, clear corneal graft. Total penetrating keratoplasty, involving replacement of the entire cornea, with or without some of the adjacent conjunctiva or sclera, has been tried many times, but the results have always been poor and have frequently necessitated subsequent enucleation.¹ Hence, the most popular operation at present is a circumscribed penetrating keratoplasty. In this procedure, windows 4 to 6 mm. wide are cut through the full thickness of the opaque cornea and replaced with pieces of clear corneas from enucleated eyes.

As with skin grafts, one also speaks of autotransplants (in the same individual), homotransplants (in the same species) and heterotransplants (between species, as from cat to man). The first and second appear to work equally satisfactorily, but heterotransplants, despite some temporary improvement, have never given a successful result in either man or animals.

Numerous methods of transplantation on both animals and human beings have been tried by many surgeons during the past hundred years, but only during the last two decades has clinical improve-

ment ceased to be regarded as a minor miracle. During the 1920's, Elschnig,² in Prague, and Filatow,³ in Odessa, did a large number of round transplants with trephines, with a few good results. In 1930, Thomas,⁴ in England, made an important contribution by beveling the edges of his trephine grafts. He⁵ has had many excellent results since that time. In 1932, Castrovicjo,⁶ in New York, published his first animal experiments, and since then he⁷ has made a greater number of important contributions to this subject, both clinically and experimentally, than any other ophthalmic surgeon.

The object of corneal transplantation is to restore sight to eyes blinded by opacities in the corneas. Unfortunately, not all such cases are suitable for operation. Favorable cases are those in which the eye is normal except for the cornea, the leukoma or scar is not dense or vascular; and there are areas of clear or slightly scarred cornea surrounding the graft to furnish it nutrition. Especially unfavorable cases are those with dense scarring of the entire cornea or with a vascularized pannus, such as that which comes from old trachoma. The eye can sometimes be rendered suitable for operation in the latter type by removing the pannus and using diathermy to seal the vessels at the corneal margin. Eyes with an old interstitial keratitis or conical cornea are unusually satisfactory cases for transplantation.

Another limiting factor in this field of surgery is the availability of donor eyes. Any enucleated eye with a clear cornea can be used. Such corneas are found in cases of intraocular tumor or blind and painful glaucomatous eyes where the cornea is edematous but has not yet degenerated. Eyes from newborn babies are also often used. Fresh material is best, but fair results are reported in eyes refrigerated for twenty-four hours.

Methods of operation are numerous. The most successful one is the graft developed by Castrovicjo.⁸ A square is cut two thirds of the way through the cornea with a double parallel-bladed knife. An oblique penetrating incision is made in the anterior chamber with a small triangular knife, or keratome, at the upper margin of this square. The square is then excised with special scissors, leaving the edges slightly beveled. The transplant is cut from the donor eye with the same knife and carefully slid into place from a flat spatula. The beveled edge on the host keeps this graft from getting lost in the anterior chamber, and several cleverly designed cross-stitches help prevent external dislocation.

*Instructor in ophthalmology, Harvard Medical School; assistant surgeon, Massachusetts Eye and Ear Infirmary, Boston; ophthalmic surgeon, St. John's, Lowell General, and St. Joseph's hospitals, Lowell, Massachusetts.

The circular graft of Thomas⁵ is also fairly satisfactory. A trephine hole is made two thirds of the way through the cornea, then continued at an angle so that an oblique penetration is made on one side. The cutting is completed with scissors, leaving a slight bevel. The graft is held in place with one vertical and one horizontal cross-stitch. Castroviejo⁷ has also perfected a modification of this method. Although I have never tried the Thomas stitch, I believe that the Castroviejo suturing is considerably more efficient.

Recently Wiener and Alvis⁹ introduced a method of cutting a slightly beveled graft with a corneal punch inserted through an incision near the corneal margin. This is by far the easiest procedure to carry out and the graft fits perfectly, but so few cases have been done by this method that its exact value is still unsettled. The peripheral incision probably does not hinder healing, but it leads to formation of anterior synechias or adhesions if a previous iridectomy has not been done. The synechias, of course, increase the danger of glaucoma. With this method, furthermore, unless the sutures are placed quite far out on the cornea it is easy to cut one when the bite is made; and if cut, a suture cannot safely be replaced.

Following operation, the patient is kept quiet in bed for ten to twelve days, and both eyes are covered for eighteen to twenty days. The pupil is kept dilated with atropine. The transient edema of the graft passes off during the first two or three weeks, and at the end of one month all but the periphery of the graft is clear and union is quite firm. Microscopic sections show conclusively that a successful graft retains its cellular identity and is not replaced by new tissue.

In unfavorable cases the graft usually takes, but soon becomes cloudy because of vascularization, proliferation of connective tissue on the back of the cornea or low-grade degenerative changes in the deep corneal layers, with loss of the normal parallel fiber arrangement there.

My own practical experience with keratoplasty has been limited to the last four years. The actual operation on human beings was approached in a rather guarded manner, with the result that up to the end of 1941 I had completed only 10 cases, one patient at that time having had a clear corneal graft for three and a half years. Because of this early caution, all these cases were classed as unfavorable in that they had dense or complete corneal scarring, vascularization or another ocular defect, such as former glaucoma or cataracts, nystagmus, chorioretinitis or extremely advanced and still active corneal dystrophy. The operation was also limited to eyes that had less than 5/200 visual

acuity and that, in addition, had a markedly defective companion eye.

The results were surprisingly good, however, since all grafts took, and all cases were improved (Fig. 1). The poorest result was in a case of vascularized and thickened complete leukoma of the cornea, which a keratoplastic surgeon in another city had refused to treat. The patient's vision six months after operation was limited to hand movements, but his original vision had been reduced to poor light projection with the ordinary flashlight, and he regarded himself as seeing considerably better. A patient treated recently also had a cataract, but it was thought best to do the transplantation first. As he has not yet had the cataract extraction, his vision is still poor; the graft, however, is crystal clear, so that the visual result will probably be good. The other cases have shown marked improvement, and several of the patients can read ordinary book print, including 2 patients with nystagmus and 2 with considerable myopia. Despite this ability to read, however, no patient has better than 20/70 vision.

These operations were done with the square graft of Castroviejo. More recently, however, I did my first punch-type transplantation. The graft took and was clear, but it had apparently slipped down slightly, leaving a tiny gap superiorly. This was the first time I had had any leakage from a wound. At the end of three weeks a conjunctival flap was put across the defect and at present it is still in situ. As the graft was transparent at the time of the flap, a satisfactory outcome is hoped for.

* * *

It is obvious from the work done in this field that corneal transplantation is a practical and not too dangerous operation. It seems best, however, to follow the custom already adopted elsewhere of operating on suitable cases with vision of 15/200 or less rather than selecting only the few extremely bad cases. As these corneas are more favorable to work on, future results may well include some normal or near-normal visual acuities.

CLINICAL NOTE

PELLET IMPLANTATION*

THE SUBCUTANEOUS IMPLANTATION OF CRYSTALLINE PELLETS OF HORMONE

MICHAEL DI MAIO, M.D.,† AND
CLARENCE E. BIRD, M.D.‡

PROVIDENCE, RHODE ISLAND

SINCE the investigations of Deanesly and Parkes^{1, 2} on the subcutaneous implantation of crystals or compressed tablets (pellets) of androgens and estrogens, many papers have appeared in the literature describing this method of administering hormones of various types. These authors have shown that pellet implants are especially desirable when a prolonged steady effect is required, thus obviating the necessity of frequent injections of hormone over long periods of time. Using pellets of desoxycorticosterone acetate subcutaneously in adrenalectomized dogs and later in patients with Addison's disease, Thorn and his associates^{3, 4} reported excellent results and emphasized the advantages of administering hormone in pellet form. As a result of this advance in the treatment of certain hormonal deficiencies, a number of reports^{3, 5, 6} have appeared in the literature describing ways and means of facilitating the operative implantation of pellets of crystalline hormone subcutaneously.

This paper describes another operative technic that has been found successful in the subcutaneous implantation of pellets of desoxycorticosterone acetate in patients with adrenal insufficiency. It is believed that this procedure may be successfully employed to implant crystalline pellets of other hormones as well.

Implantation should be performed in the operating room under the usual aseptic precautions. The necessary instruments are simple and are found in most hospitals. The essential material is as follows: trocar and cannula (Fig. 1); glass rod; hypodermic syringe and needles; 1 per cent solution of novocain; scalpel; and suture material.

Experience has shown that this is best suited for patients. After a routine skin wheal is made with a long needle the

infrascapular region (Fig. 1A), an intracutaneous novocain block of the tissues is

infiltrated within an area of several centimeters. An incision about 1 cm. in length is made at the anesthetized site. A trocar with attached cannula

FIGURE 1. Photograph of Trocar and Cannula.

is easily introduced through the skin opening and gently forced into the subcutaneous tissue (Fig. 2B). The trocar is withdrawn, leaving the cannula in place (Fig. 2C). With forceps a pellet is

FIGURE 2.

ed into the lumen of the cannula and pushed into place with the aid of a glass rod (Fig. 2D). The pellet is held gently in place by the rod. The cannula is carefully withdrawn for about 15

*Medical Service and the

Rhode Island.

Rhode Island

cm.* The glass rod is then completely removed and a second pellet is directed into place in a similar manner. The procedure may be repeated if a third pellet is to be implanted on the same side, but the operator should make certain that the cannula is withdrawn a short distance when each pellet is in place (Fig. 2E).

Following the implantation of one, two or more pellets on one side of the incision, the cannula is completely withdrawn. If more pellets are to be implanted, the trocar with cannula is inserted through the same skin opening but in the opposite direction, and the procedure is repeated. Should the patient's condition require inserting a large number of pellets, this is readily done by directing the trocar in other directions, always using the original incision (Fig. 2F). A single suture is all that is necessary to close the wound.

This procedure has many advantages. It has proved to be simple, short and effective. Trauma to the tissues is held at a minimum. Bleeding is negligible and hemostasis is not necessary. The gentle handling of pellets is assured; this is important, since crushing of one or more pellets may be harmful. Furthermore, since pellets are placed

several centimeters from the incision they are not easily extruded, as has occasionally been found to be true with other procedures. The clumping of pellets does not occur. Virtually any desired number of pellets may be implanted without difficulty. Likewise, the arrangement facilitates the location and removal of one or more pellets through a small incision should the occasion demand it.

SUMMARY

A simple, short operative technic has been described for the implantation of pellets of hormone under the skin with the aid of a trocar and cannula.

MEDICAL PROGRESS

THE USE OF DRUGS IN THE TREATMENT OF ASTHMA

FRANCIS M. RACKEMANN, M.D.*

BOSTON

MANY articles have been written on the use of drugs in the treatment of asthma in the last few years, but there still seem to be difficulties and misunderstandings in various directions. It is consequently worth while to review the recent knowledge and to add one or two personal observations.

EPINEPHRINE (ADRENALIN)

When a patient is younger than thirty-five and the onset of asthma was before or about the age of twenty, the chances are good that the cause is not some pathologic lesion (intrinsic factor), but that it depends on a hypersensitiveness to a food, dust or drug in the environment (extrinsic factor). In such a case it is quite proper to inject a small dose

of epinephrine subcutaneously. If the attack is relieved, further doses can be given three, four or perhaps six times every twenty-four hours while the patient is at home. If, however, the asthma is severe and the doses of epinephrine have only a slight and transient effect, the patient should be removed to a hospital. The details of further treatment are relatively unimportant. Such patients will almost surely do well in the hospital, simply because they have escaped from the causative substance at home. The doctor should not be over-anxious to relieve the wheeze during the first few hours after admission. If the cause is a dust and the patient has escaped, the asthma will clear by itself. Also, the fatigue and anxiety which go with asthma will improve with the nursing care and the reassurance that are so important a part of the hospital management.

Epinephrine is the blood-pressure-raising constituent of the adrenal gland isolated by Abel¹ in

¹The articles in the medical progress series of 1941 have been published in book form (*Medical Progress Series*, Volume III, 178 pp. Springfield, Ill., Charles C. Thomas Company, 1942, \$5.00).

*Lecturer in medicine, Harvard Medical School, Boston; Massachusetts General Hospital, Boston.

1897, and renamed "Adrenalin" by Takamine² a few years later. It is a sympathicomimetic substance the function of which is to stimulate the sympathetic nerves to make them overcome the action of the vagus nerves, which produce the asthma. In most cases the stimulation is effective, but if the drug is used repeatedly or given in too large doses, after a time the sympathetic nerves become overstimulated and the nerve-muscle cannot respond. The epinephrine is then said to have lost its effect.

The symptom asthma may be produced by a spasm of the smooth muscles in the bronchial wall, by a swelling of the mucous membrane or by an overactivity of the mucous glands. One or another of these results in a narrowing of the bronchial lumen and so in a wheeze. Whether the effect depends on a central and therefore a direct nerve stimulation or on the local action of some chemical effector substance like histamine or acetylcholine, which acts directly on the effector organ—the mucosa, the muscle or the glands—is still debatable, but the fact is that the result is a diffuse process which causes the signs of asthma to be fairly evenly distributed throughout the lung. In typical extrinsic asthma the signs are not limited to any one area.

Epinephrine is sometimes called on to stop the cough from bronchitis, with its mucus in the lumens of the bronchi, the dyspnea of heart disease, with its engorgement of pulmonary blood vessels, or the dyspnea of organic emphysema, with its dilatation and coalescence of terminal alveoli and its large spaces filled with air. But the drug cannot relieve these conditions: it is effective only when the symptoms are due to excessive vagal stimulation.

The dosage of epinephrine is important. When the correct dose is given to the right patient, the asthma is relieved, no new symptoms develop, and no harm results. When, however, too much epinephrine is used, the asthma itself may improve but the patient feels "queer." He turns pale and sweats slightly, the hands become cold, and the pulse becomes rapid and the heart pounds. There may be headache, and with all this a sense of weakness and collapse. In some ways the picture resembles that of surgical shock, but the blood pressure is usually higher, not lower, than normal. These side effects depend obviously on the stimulation of other parts of the sympathetic system. Thus, the heart is stimulated and the blood pressure rises; if continued, the effect may result in auricular fibrillation. As an example of severe reactions, a man of forty-two was seen at home on the third day of a severe asthmatic attack. His wife had given him epinephrine every 2 hours as

instructed, but the drug ceased to be effective. Unfortunately, the pallor, sweating and rapid pulse observed were not recognized as due to an excess of the drug, but were attributed to fatigue and loss of sleep. Still more epinephrine was injected. Within a few minutes the shock increased. The breathing became shallow, and the patient became almost unconscious. He was given $\frac{1}{4}$ gr. of morphine and hurried to the hospital. An intravenous infusion of 5 per cent glucose in physiologic saline solution was started and the patient rallied, his color and pulse returning to normal.

Such reactions from the injection of watery solutions of epinephrine are, however, infrequent. Keeney³ reports the case of a man of thirty-three who was given 0.5 cc. of a 1:1000 dilution by hypodermic injection. Violent headache with coma developed in a few seconds. The next day the patient had a right hemiplegia. He recovered slowly. The drug may have been injected intravenously by accident; many lesser reactions have come from that circumstance.

Three practical points are worthy of emphasis. In the first place, epinephrine is effective only when the patient's symptoms depend on spasm of the bronchial muscles or swelling of the bronchial mucosa. Secondly a small dose, that is, 0.25 cc., is usually quite as effective as a larger one. Patients vary in this regard, however, and it may happen that a given patient requires a large quantity. One should begin with a small dose and increase it gradually until the desired effect is obtained, after which it may be possible to reduce it. If the first dose is ineffective, a second may be injected in about fifteen minutes. Such pairs of doses, however, should not be given oftener than two hours apart. The intravenous injection of 1 liter of physiologic saline solution containing 1 cc. of a 1:1000 dilution of epinephrine is a useful procedure in cases of critical severity. And, finally, too much epinephrine does much more harm than good. If the patient has had repeated injections with no effect, the administration of further quantities may lead to serious difficulties.

High blood pressure is not a contraindication to the drug provided that bronchial spasm is present at the same time. When this bronchial spasm is relieved, the burden on the heart is lightened and the blood pressure goes down.

The effect of epinephrine appears within fifteen minutes. It may persist for many hours, but in most cases it lasts for not more than two to four hours. Efforts to prolong the effect have been made.

The administration of epinephrine in oil was suggested in 1938 by Keeney.⁴ The powdered base is suspended (not dissolved) in sterile peanut oil—

2 mg. per cubic centimeter or a 1:500 suspension. In Keeney's first experiment olive oil was used, but later he and his associates⁵ found that peanut oil was less irritating, since it contains less fatty acid. The usual dose is a whole ampule, or 1 cc. For some patients, the method is satisfactory, and the asthma is relieved for a longer period than it is by the ordinary watery solution. The fact that the speed with which relief of symptoms comes is about the same with oily as with watery epinephrine indicates that absorption at least begins promptly.

Reactions to epinephrine in oil, however, are not infrequent. In a recent paper, Keeney⁶ has reviewed them. Local reactions, consisting of redness, swelling and pain at the site of injection, depend on the presence of an irritating fatty acid in the oil or, more rarely, on an allergic response to the oil itself. More important are the systemic reactions. Symptoms of overdosage—pallor, palpitation and nervousness—not infrequently follow doses of oily epinephrine. Keeney reports 4 cases in which the symptoms were alarming. He points out that the large needle required for the oily mixture leads to rapid injection, and that the danger of placing the material in a blood vessel is greater than when the injection is given more slowly and through a smaller needle. Since in oil the epinephrine is present in a strength of 1:500 instead of 1:1000, one should be particularly careful not to inject the dose into a vein. Whether trouble comes because the epinephrine is a suspension of dry particles rather than a true solution Keeney considers doubtful. Dorwart⁷ reports the case of a woman of twenty-two with asthma who was given 0.3 cc. of 1:1000 aqueous epinephrine and at the same time 1.0 cc. of oily epinephrine. Within a few minutes there occurred shaking, pallor, twitching and cyanosis, with a pulse rate of 160, and the patient's condition became desperate. It was relieved temporarily by tourniquets, but she was not out of danger for five hours. More recently Maietta⁸ has reported that of 14 patients treated with epinephrine in oil, 2 had severe reactions. A man of thirty-seven with severe asthma was given 0.4 cc. of watery epinephrine and ten minutes later 1.0 cc. of epinephrine in oil. The effect was severe for one and a half hours. An obese woman of thirty-eight suffering from asthma of moderate severity was given only 0.4 cc. of epinephrine in oil. Within an hour came blanching at the site, followed by redness and swelling, which spread over the shoulder, arm and forearm. The local lesion lasted for six days.

Gelatin provides another medium for the administration of epinephrine, as Spain, Strauss and Fuchs⁹ have described. It is prepared by adding

one part of a 1:100 aqueous solution of the drug to four parts of an aqueous solution containing glycerin, sodium chloride, sodium bisulfite and chlorbutanol. At room temperature this solution gels, so that the ampule must be warmed before injection. The usual dose of 1 cc. contains 2.0 mg. of epinephrine. It can be given subcutaneously. In 50 cases the results were good and no untoward reactions were observed. Miller et al.¹⁰ have used epinephrine in gelatin in over 200 cases, and find it useful.

Epinephrine given as a spray to be inhaled directly into the bronchi was used first by Graesser and Rowe¹¹ in 1935. A relatively strong (1:100) dilution was employed—generally in a special fine nebulizer—and a large number of asthmatic patients were treated. If the bronchospasm was not severe, this method was found to be effective. Gagliani et al.¹² calculate that each squeeze of the bulb discharges only 0.008 mg. of epinephrine. Even so, they found that when rabbits and cats were given ten squeezes of this solution each day, after four months there was a loss of cilia and a desquamation of the tracheal and bronchial epithelium in some of the animals. Another slight risk is that the bottle of the former 1:100 epinephrine may be mistaken for that of the ordinary 1:1000 solution, and that a dose of the former may be injected subcutaneously. In one such case reported by Gormsen¹³ the patient died in a few minutes from a dose of 0.6 cc. (60 mg. of epinephrine) of the solution.

New products designed as substitutes for epinephrine have recently been reviewed by the Council on Pharmacy and Chemistry.¹⁴ Vaponefrin contains racemic epinephrine having the levorotatory and dextrorotatory isomers in equal parts (epinephrine *U.S.P.* is purely levorotatory). The dextrorotatory isomer is the much less active of the two, but analysis has shown that whereas the material as prepared contains 23 mg. of substance per cubic centimeter, it has a physiologic activity equivalent to that of 1:40 dilution of epinephrine. Vaponefrin is sold only to physicians, but products entirely similar are sold to the public under such trade names as Asthmanefrin, Neosol (also called Solution A or Inhalant A) and Nephron (also called Solution N or Inhalant N). Each of these is active and effective but expensive, as Barach and his assistants¹⁵ point out.

Epinephrine consists chemically of a benzol ring with two hydroxyl (OH) groups and a chain made up of two carbon and one nitrogen atoms. The hydroxyl groups on the ring make the compound unstable and give it optical activity. Further details concerning epinephrine appear in a comprehensive paper by Cori and Welch.¹⁶

EPHEDRINE

Ephedrine is closely related to epinephrine. It has no hydroxyl (OH) group in the benzene ring so that it is stable and is not optically active. The drug is useful in asthma; it is absorbed by mouth and controls mild bronchospasm. Its action is slow, and the dose, 20 to 40 mg. ($\frac{3}{8}$ to $\frac{3}{4}$ gr.), should be taken after supper if the effect is to be obtained at bedtime. Too much ephedrine may cause palpitation and tachycardia. The commonest difficulty, however, is that the drug causes sleeplessness, and on this account ephedrine has been mixed in various proportions with barbiturates and dispensed in capsules of many colors by different drug companies. Ephedrine is worth a try, perhaps, but if it does not control the symptoms, the patient should be given epinephrine, in place of forcing the dose of ephedrine to high levels. An interesting innovation is that of Brown,¹⁷ who coated ephedrine with a wax so as to delay its absorption for about three hours. By taking this tablet at bedtime, together with a dose of regular ephedrine, the patient receives a new dose of ephedrine automatically at about the time when the effect of the regular ephedrine is wearing off.

AMINOPHYLLINE

Aminophylline is a combination of theophylline with ethylene diamine. It was first used in 1937 by Herrmann and Aynesworth¹⁸ as a treatment for severe asthma. In the same year appeared a paper by Greene, Paul and Feller¹⁹ in which the drug was advised as a treatment for cardiac failure. These authors found that after the drug was given the breathing improved and the pressures in the vein and in the spinal fluid rose.

Theophylline is a xanthine derivative related to caffeine and to theobromine. All these drugs have a diuretic action, presumably because they improve the transport of fluid through the kidney capillaries. The addition of ethylene diamine to theophylline renders the mixture much more soluble, so that the combination called aminophylline is much more effective than is theophylline by itself.

In asthma the effect is good. Young and Gilbert²⁰ believe that aminophylline has a protective action against the bronchial constrictor effect of histamine. In guinea pigs, histamine shock and anaphylactic shock are both inhibited if the test dose is preceded immediately by an injection of aminophylline. So far, the mechanism that results in the relief of asthma by aminophylline is not clear.

Aminophylline must be given intravenously. If given subcutaneously it is much less effective, and furthermore it is irritating to the tissues. The dose

for intravenous injection to the average patient is 200 mg. ($3\frac{3}{8}$ gr.), which is dissolved in 10 cc. of water and comes prepared in ampules. A larger quantity, up to 400 mg., has been used, but is no more effective than the smaller dose.

Another preparation consists of 400 mg. dissolved in only 2 cc. of fluid. Supposedly this preparation is for intramuscular use. Occasionally, however, this concentrated material is given by vein; in such cases the patient has a sense of flushing and warmth, with palpitation and weakness, that may be quite troublesome. So far, severe and dangerous reactions following the use of aminophylline have not been described. Lamson and Bacon²¹ have used it freely, and even though their clinical description is long and complete, they say little about untoward effects. Incidentally, they find that the symptoms of hay fever and urticaria are improved by aminophylline quite as much as are the symptoms of asthma.

Aminophylline is prescribed in doses by mouth. The literature contains little about this topic, perhaps because the effect is hard to evaluate; certainly it is rarely striking. In the Allergy Clinic of the Massachusetts General Hospital, aminophylline is given in pills containing 0.2 gm. (3 gr.), to be taken three or four times a day. Several commercial preparations contain 2 gr. of theophylline in combination with $\frac{3}{8}$ gr. of ephedrine and $\frac{1}{8}$ gr. of phenobarbital. One in common use has 2 gr. of aminophylline in a similar mixture. Many patients declare that the ingestion of one, two or three of these tablets or capsules each day seems to protect them from their attacks. No doubt more are consumed than are really necessary.

WATER, SALT AND SUGAR

Almost all patients with severe symptoms that cannot be easily controlled should be given an intravenous injection of normal salt solution, usually containing 5 per cent glucose; a relatively large amount (1500 cc. or more) is allowed to run in with fair speed. In most cases the effect of this simple procedure is prompt and satisfactory. Patients with severe asthma cannot eat or drink. They have a tired, pinched expression, the tongue is parched, and they are dehydrated. To give such a person 1500 cc. of water containing 12 gm. of sodium chloride and 75 gm. of glucose helps very considerably. Sometimes improvement from this treatment begins promptly and develops dramatically when only 300 or 400 cc. has been run in.

The mechanism of this improvement is not at all clear. So far no studies of blood constituents or of the distribution of electrolytes have been made in asthma, and the field needs cultivation. Whether the addition of sugar accomplishes anything more

than providing a little food seems doubtful. In 1937 Wagner and Rackemann,²² among others, studied the glucose tolerance of patients with severe asthma, some of whom were in status asthmaticus, but found that the curve was like that for normal nonasthmatic subjects. The sugar metabolism in asthma appeared to be normal. Whether the injection of physiologic salt solution by itself without the addition of glucose is equally effective can be determined easily, but curiously it has not been tried in any series of cases.

Hypertonic glucose solutions have been advocated. In 1934 Lepak²³ at the Mayo Clinic treated 4 cases of severe asthma by injecting intravenously 100 cc. of 50 per cent glucose on each of two or three days and claimed good results. In 1938 Stoesser and Cook²⁴ gave similar treatment but in smaller doses to 3 children, and found that when the asthma was due to food allergy the attack was relieved, but when it was due to dusts the effect was not so good. Incidentally, children without associated pharyngitis and bronchitis responded better than did children with these secondary infections. In the same year Keeney²⁵ treated 6 patients with one or more intravenous injections of 100 cc. of 50 per cent sucrose (not glucose) to which had been added 0.5 cc. of a 1:1000 solution of adrenalin. In all, twelve injections were given, and with only two exceptions there was immediate relief from asthma, which lasted for at least two and a half hours. Stoesser and Cook²⁴ also used sucrose, but not with such good results.

OTHER DRUGS

Potassium salts. Potassium iodide has been described as the "sheet anchor" in the treatment of asthma. Most authors consider that its effect depends on its excretion into the bronchial tubes, where it irritates the mucous membrane and the mucous glands and so increases bronchial secretion. In this mechanism more stress has been laid on the iodine than on the potassium radical. Now, however, there is evidence that the potassium radical may be important. In 1938, Rusk and Kenamore²⁶ made the interesting observation that the injection of epinephrine causes an increase in the potassium concentration of the blood serum, and also that the intravenous injection of potassium salts relieves the symptoms of urticaria. Potassium lowers the irritability of the skin, making it less responsive to local irritation. Putting these facts together, the authors devised a "potassium regime." They made the diet low in sodium and high in potassium for the treatment of urticaria and of allergy. In the next year Rusk and his co-workers²⁷ found that potassium is stored in the tissue cells of the body, and that in allergy this store is depleted. Keys²⁸

found that after the giving of epinephrine the plasma potassium falls but returns to normal in about twenty minutes. Evidently epinephrine produces a change in the distribution of the potassium between cells and plasma. Since 1938 the use of potassium chloride has been discussed frequently, but unfortunately with no unanimity of opinion. Cohen²⁹ used the diet and the potassium chloride that Rusk and Kenamore advised, but saw no change in 8 patients. Bloom,³⁰ however, declared that it produced striking benefit in 29 cases of hay fever. Rusk himself gave potassium salts to 30 patients with hay fever, but with good effect in only 3 of them. Fürstenberg and Gay³¹ gave potassium chloride to 85 per cent of the patients in the clinic at Johns Hopkins Hospital, varying the doses and technic considerably, but the results were uniformly poor. Harsh and Donovan³² gave potassium chloride up to 18 gm. per day but were not at all satisfied that it did any good, for, as they point out, other factors could explain the small variations in the symptoms described. Obviously, there is much to learn about the physiology of allergy, especially of the asthmatic attack, and as said before, one can hope that accurate and complete data on the subject will be forthcoming.

Insulin. Bruhl³³ found that the intravenous injection of 10 units of insulin—he called it the "insulin thrust"—was useful in allergic skin disease, especially urticaria, and he tried the method in asthma, hay fever and mucous colitis. He is convinced that it is possible to influence allergic processes with insulin therapy. Insulin burns up sugar and lowers the blood-sugar level, and its effect is quite opposite to that of hypertonic glucose solutions. The results claimed for the "insulin thrust" make the problem even more confusing.

Sodium thiosulfate. The use of this drug is advocated by Klein³⁴ on the basis of some alteration in the body colloids. He has used it both by mouth and by vein in allergic epilepsy, in migraine and in urticaria, and declares that his results have been unusually excellent.

Amino acids. Tryptophan and histidine have been used by Lenormand,³⁵ who believes that they stimulate a hypersecretion of mucus, which in turn protects the hypersensitive membrane.

General anesthesia. It has been frequently observed that general anesthesia stops asthma temporarily. Perhaps this explains some of the beneficial results claimed for various operations that have been advised in the treatment of asthma. Anesthesia without operation has been tried; although this may provide temporary relief, the results are not so good as they are when some operation is combined with it. The prolonged

effect of the latter may depend on tissue injury, with the subsequent absorption of tissue-degradation products.

Ether. Ether in oil by rectum has been used occasionally. The results are satisfactory, and the mixture is not nearly so irritating to the bowel wall as one might expect. The dose is 30 cc. of ether and 30 cc. of olive oil, shaken well together and injected slowly into the rectum once, twice or even three times a day, if necessary.

Dilantin Sodium. This drug has been used as an anticonvulsant in epilepsy. Quite recently Shulman³⁶ gave Dilantin to 7 children with asthma in doses of 10 to 20 mg. (1½ to 3 gr.) per day and found the results good. The relief was maintained by continuing the drug in small doses once or twice a day. One must observe, however, that in children especially severe attacks of asthma are often followed by a remission, particularly if the patient is in a hospital.

Niacin (nicotinic acid). Maisel and Somkin³⁷ gave 100 mg. of niacin by intravenous injection to 20 patients with severe asthma. Sixteen of them were relieved within a few minutes. To 9 other patients doses of 200 mg. were given each day by mouth, and 5 were benefited. The use of this drug deserves further study.

Sulfonamides. The sulfonamide drugs have been used in asthma (Unger³⁸), and it is inevitable that many reports about them will be published. So far, however, the results are not encouraging, and the reason seems clear. Asthma does not depend on an acute infectious process. If bacteria are concerned, it is only because they have produced some chronic infection in the bronchi or nasal sinuses, and it is evident that the chronic process is always associated with pus. Since pus antagonizes the bacteriostatic action of the sulfonamides, in such cases the drug has little effect on the bacteria. To use sulfonamide drugs in asthma is like using epinephrine for heart disease: one is asking the drug to do something that it cannot do.

Histamine. The relation of histamine to allergy and asthma is always interesting. Dzsinich³⁹ first called attention to the treatment of allergic persons by giving them small doses of histamine. Little attention was paid to his work until Farmer and his co-workers⁴⁰ became interested in the clinical use of histamine. Histamine and acetylcholine are two substances that are normally present in the body tissues and are released by injuries to these tissues. Histamine comes from muscle and connective tissue, whereas acetylcholine comes from nerves. Together they are referred to as "cholinergic" substances. It is a temptation to consider them as the common denominators that give rise to the symptoms of hay fever and asthma,

a relatively uniform picture that is activated by a wide variety of exciting causes. To consider that asthma depends on an over-reaction to histamine or perhaps to an excess of histamine production is tempting, and so it is natural to consider the administration of histamine in an attempt to modify the natural reaction to it. So far the method is still experimental, and is not without danger, since histamine is a potent drug and doses above a certain limit are likely to cause reactions of considerable severity. Particularly in asthma, the treatment if given unwisely can easily precipitate an attack of great severity. The treatment gives some promise, but the details need careful study, and for the moment they had better be left to those who are thoroughly familiar with the drug and with the reactions that it produces.

Ether in oil from an ampule containing 1 cc. of ether and 1 cc. of peanut oil to be injected intramuscularly has been advocated by Maietta.⁴¹ Four patients with acute asthma were relieved by only one dose, and 2 others required two doses. In a group of patients who had had asthma for thirty or forty years, ether in oil given once or twice a week seemed to reduce the severity of the disease and to make other treatment more effective. And, finally, 2 patients with status asthmaticus were given ether in oil at intervals of 4 to 6 hours, with benefit. According to this first report the drug is useful.

DRUG ALLERGY

The literature on drug allergy is extensive, and part of it was reviewed in these columns in 1941.⁴² The symptoms are varied; they may be severe, and they appear when least expected. Three drugs are pertinent to the present discussion. *Aspirin* may be effective in asthma, but it should never be given without inquiring carefully whether the patient has ever had trouble from aspirin or other salicylates. Those patients sensitive to aspirin constitute a serious and difficult group. *Barbiturates* of all kinds are in a similar category. A hypersensitiveness to them may be present, and a pill taken to induce sleep—or, more important, a commercial preparation that contains phenobarbital—may not only fail to induce sleep in the patient, but may lead to a bad night for the doctor as well. The situation can become alarming. *Morphine* is important. I believe that it should never be used in asthma, although, in the case cited earlier I did give it when too much epinephrine had created a critical situation. Morphine is a cholinergic drug: it can actually cause bronchospasm. Furthermore, in severe asthma when the patient is gasping for breath, depression of the respiratory center may be the last straw. As the old darky said:

"Sam had the asthma powerful bad, but dat doctor is a great man. After he come, Sam he died jess so quiet."

* * *

From all this, it is quite clear that in asthma, as in other diseases, success in the use of drugs depends on the happy correlation of the physiologic mechanism of symptoms with the pharmacologic effects of the drug selected. To expect drugs to have an effect on a process that they cannot influence leads to discouragement, and some times to disaster.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 29121

PRESENTATION OF CASE

A seventy-five-year-old Massachusetts-born farmer entered the hospital with the complaint of difficulty in swallowing of about ten years' duration.

Some fifteen years before entry he began to have "dyspepsia." This was characterized by slight pain in the "pit of his stomach" and much gas but no nausea or vomiting, and had no relation to the intake of food. An x-ray examination was alleged to have shown a "fallen stomach," and for some years the patient slept with his feet higher than his head, with apparent relief. About five years later he first noticed slight difficulty in swallowing large objects. Two years before entry he had great difficulty one day in swallowing a raisin, and only after an hour and the eating of considerable soft pudding did it finally slip along. Since that time solid food particles frequently stuck at a level that seemed to be slightly below the larynx. Ordinarily he was able to milk them down by rubbing his neck from above downward. No progression in the degree of obstruction was noted, although he ate only soft foods, until two days before entry, when he was completely unable to swallow a mouthful of custard pie. He had eaten nothing since then but had been able to swallow saliva and water. Throughout the ten-year period he had had no pain, nausea, regurgitation or vomiting. He had not lost weight and there had been no cough, hoarseness or change in character of the voice.

The family and marital histories were noncontributory. The patient had habitual constipation and had taken a phenolphthalein laxative daily for many years. For an unspecified period of many years he had been edentulous, and he had not recently used dentures because of soreness of his gums.

Physical examination showed a well-developed and well-nourished man with dry lips and skin. The gums were swollen, reddened and hypertrophic. No masses or tenderness could be made out in the neck. The lungs were normal. The cardiac apex impulse was neither seen nor felt

but the heart did not seem to be enlarged. The sounds were of good quality and there were no murmurs. The rhythm was regular. The abdomen was soft, without spasm or tenderness. One examiner recorded a questionable mass just below the xiphoid. There were bilateral, reducible inguinal hernias. The prostate was slightly enlarged but soft.

The blood pressure was 146 systolic, 92 diastolic. The temperature, pulse and respirations were normal.

Laboratory studies showed a urine with a specific gravity of 1.020 and no albumin or sugar. Blood examination showed a red-cell count of 4,300,000 with a hemoglobin of 78 per cent. The white count was 9500, and the differential showed 84 per cent polymorphonuclear leukocytes, without other noteworthy features. The blood protein was 6.3 gm. and the nonprotein nitrogen 20 mg. per 100 cc. The blood chlorides were 104.6 milliequiv. per liter.

Fluid barium taken by mouth filled the hypopharynx and upper 2.5 cm. of the esophagus, dilating the latter. The barium then met an obstruction at the level of the manubrium, and repeated efforts at deglutition failed to force barium past this point. Spot films showed a rounded collection of barium approximately 2.5 cm. in diameter above this point of obstruction.

The day after entry a biopsy was performed on the hypertrophic gum and an esophagoscopy was done. At the junction of the upper and middle thirds of the esophagus, 18 cm. from the anterior tooth line, an obstruction was encountered. There the mucous membrane was thrown into puckered folds but showed no break or ulceration. Soft bougies could be passed up to and including a No. 24. The esophagoscope did not pass. Several bits of tissue were taken for biopsy. Histologic examination of the two sets of specimens showed chronic gingivitis and no abnormality of the esophageal mucosa.

Following instrumentation the patient coughed up some "bloody pus" and thereafter found it easier to swallow liquids. On the fifth day a Beck-Jianu gastrostomy was done. Exploration of the upper abdominal cavity was negative. Following operation he seemed comfortable, and his temperature remained normal. The chest was clear except for a few moist rales at both bases. On the morning of the fourth postoperative day he complained of generalized discomfort which he was unable to localize. Examination showed slight abdominal distention, and the abdominal wound was found to have eviscerated to but not through the skin. The lips were cyanotic. The

blood pressure was 125 systolic, 80 diastolic, and the pulse 100. The heart and lung findings were unchanged. While being prepared for an enema the patient suddenly collapsed, became pulseless and deeply cyanotic, and expired.

DIFFERENTIAL DIAGNOSIS

DR. CARROLL C. MILLER: Cases of obstruction of the esophagus can be considered under three common headings: diverticulum, stricture and carcinoma. Benign tumors of the esophagus are relatively rare; malignant tumors are of fairly common occurrence as tumors of the gastrointestinal tract go. Strictures may be congenital but more frequently they are traumatic and usually due to the scarring caused by a caustic solution taken with suicidal intent or by accident. Carcinoma of the squamous-cell type is the usual malignant tumor.

We have here an elderly man with no symptoms of difficulty previous to ten years before he was first seen. At that time he began to have obstruction of the esophagus. The symptoms at the time of the first episode are a little confusing. It is said that he had "dyspepsia," which might be indigestion or perhaps heartburn or pain in the upper abdomen. He had slight pain in the pit of his stomach and considerable gas but no nausea or vomiting. Later on the record states that there had been no regurgitation or vomiting. I am unable to relate this particular symptom of dyspepsia to what subsequently developed, except by a referred influence on the motility of the stomach or encroachment on the wall of the stomach by some process above. I am not inclined to attach much significance to this symptom, except that perhaps it was the earliest, simplest sign of trouble higher up. Often, however, patients with tumor of the esophagus have no indigestion.

The x-ray diagnosis of "fallen stomach" probably has no significance, especially in light of the abdominal exploration that was done later. We are fortunate in being able to look back on the whole picture rather than part of it, as the original clinician had to do.

The question of esophageal diverticulum is an interesting and important one. There are some points about the case that strongly suggest a diverticulum of the esophagus. Diverticula occur in three parts of the esophagus, most frequently in the upper esophagus just below the hypopharynx. These are called pulsion or sometimes traction diverticula. The next commonest are in the middle half or upper middle third.

in the region of the bifurcation of the trachea, and finally but rarely they occur in the lower portion, where the muscle fibers start to thin out to become the cardia of the stomach. A patient with an esophageal diverticulum in the upper third often complains of something sticking at the region of the larynx. This may be due either to the lodgment of food particles in the entrance to the diverticulum or to filling of the diverticulum and compression of the esophagus, causing obstruction of the main lumen. A similarly significant symptom is the story of rubbing the neck from above downward to get rid of the food. This is frequently done by patients with diverticulum of the upper part of the esophagus. The pouch is low in the neck and by massaging that pouch the material contained therein can be expressed and deglutition can progress normally. We have no progression in this case for approximately two years. I assume that the patient was going on with the same general schedule of eating soft food, of massaging his neck and of having occasional bouts in which food stuck in the neck above the larynx; suddenly he became unable to swallow anything more than saliva and water.

On physical examination there were no clinical signs of a malignant process, and the x-ray findings were also negative. Patients with carcinoma of the esophagus frequently show loss of weight because of the difficulty in eating. We have no x-ray signs that could be called conclusive of carcinoma or tumor of the esophagus. The changes in the mouth—the red and swollen hypertrophic gums—were undoubtedly due to vitamin deficiency. This man probably was not getting his full quota of vitamins. He was living on liquids and a rather limited variety of them.

There were some rather interesting x-ray studies, and we might look at the films at this point. The barium taken by mouth filled the hypopharynx and the upper 25 cm. of the esophagus, dilating that part of the esophagus.

DR. RICHARD SCHATZKI: When one looks at the x-ray films there are a few things that may be added to the report in the record. One is the fact that the obstruction apparently was unusually complete. In none of these films do I see any barium beyond the plane of obstruction. Because of the marked obstruction there was some spilling of barium into the larynx and the trachea. The other point which may be added is that the round shadow is fairly smooth in outline but is irregular at the lower border in all the films, which may be due to tumor or may be due to food. I think from the evidence we have here it is impossible to say which of the two it is.

DR. MILLER: This pocket of barium is at the level of the manubrium as stated in the report, is it not?

DR. SCHATZKI: That is correct.

DR. MILLER: As I understand the topography of the esophagus that level is less than 18 cm. from the anterior tooth line as measured in esophagoscopy. Would that agree with the 18-cm. mark?

DR. RICHARD SWEET: I think it would agree, from the tooth line.

DR. MILLER: I had the impression that the obstruction seen by esophagoscopy was lower. Now I see that this is a well-rounded barium shadow.

DR. SCHATZKI: There is one lateral film, which may have significance. This is the filled hypopharynx, and you can see the round accumulation of barium about which we are talking. Between the two there is narrowing. It may be coincidental and transient, or it may be the neck of something. I do not know. You can see the same appearance in the anteroposterior view. On the other hand it seems to lie in the midline.

DR. MILLER: The fact that it lies in the midline is rather against a diverticulum because usually they are pressed to one side or they protrude from behind the esophagus so that they extend from the esophagus laterally. There was obviously some degree of dilatation of the esophagus from prolonged obstruction. The esophagoscopy showed an obstruction, which apparently extended all the way around the esophagus. I judge from the report that the esophagus was puckered and folded in its entire surface but showed no break or ulceration. An interesting fact is that bougies could be passed up to and including No. 24, which is a moderate size, thus showing that a certain amount of dilatation was possible, but not enough to allow the esophagoscope to pass.

The patient then had an episode indicative of sepsis. Bloody pus was coughed up, and at that point it was easier for the patient to swallow liquids. The medical attendants obviously thought that surgery was warranted, and exploration was done abdominally. Apparently no abnormal lymph nodes or no abnormality of the stomach itself was found, so a Beck-Jianu gastrostomy was done. For four days the patient seemed to do well but suddenly had a bad turn, the nature of which is indeterminate except for the fact that inspection of the abdominal dressing showed that he had an evisceration through the inner layers of the abdominal wall; then came a sudden collapse.

I have a feeling that this man must have had a carcinoma of the esophagus that perforated. The pouch seen in the x-ray film represents either an abscess cavity or a dilated esophagus above the

point of constriction, which Dr. Schatzki pointed out. The instrumentation of the esophagus stirred up the infective process in the abscess cavity so that the patient coughed up bloody pus, the product of the degeneration that had occurred there. The nature of the terminal episode I cannot be sure of, and it is not particularly important in the present diagnostic problem. It may have been a cerebral embolus, or it may have been a coronary attack. We have no data to indicate whether there were any symptoms of explosive cough which might indicate rupture of an abscess or tumor into the bronchial tree and cause the patient to become deeply cyanotic. Deep cyanosis can occur either with cerebral embolus or with sudden obstruction to the air passages. My diagnosis is carcinoma of the upper third of the esophagus with abscess formation.

DR. TRACY B. MALLORY: This case somewhat resembles a case you discussed recently, Dr. Lerman. How do you feel about this one?

DR. JACOB LERMAN: I am impressed by the fact that the x-ray films did not show irregularity of the esophageal wall, which is usually present with carcinoma of the esophagus.

DR. SCHATZKI: There is some irregularity.

DR. LERMAN: The description is not that of an ulcerative lesion. At least you did not mention it when you discussed it.

DR. SCHATZKI: It is irregular, however.

DR. LERMAN: Would you say it was ulcerated? The esophagoscopist did not describe ulceration. Since the two methods of examination seem to agree I should say that that is an important argument against it. Is there evidence of an extrinsic lesion pressing on the esophagus?

DR. SCHATZKI: None is visible.

CLINICAL DIAGNOSES

Carcinoma of esophagus.

Coronary occlusion?

DR. MILLER'S DIAGNOSIS

Carcinoma of the esophagus, with perforation and local abscess formation.

ANATOMICAL DIAGNOSES

(Cardiospasm.)

Esophagitis, acute, ulcerative.

Gastritis, acute, with pseudopolyposis.

Bronchopneumonia.

Pulmonary edema.

Pulmonary congestion.

Hydrothorax, bilateral.

Hydropericardium.

Cardiac hypertrophy, hypertensive type.

Arteriosclerosis, marked coronary and moderate aortic.

Nephritis, chronic vascular, slight.

Cortical cysts of kidney.

Operative incision: gastrostomy.

Incisional hernia.

PATHOLOGICAL DISCUSSION

DR. MALLORY: The autopsy was done with the esophagoscopist present. He readily passed his instrument at the autopsy table, meeting no obstruction. On removing the esophagus we found that the first 1.5 cm. of the esophagus was normal. Below that point the wall was edematous and three or four shallow, apparently acute ulcerations were present in the esophageal mucosa. From there on down to the cardia the esophagus was markedly dilated and the wall extremely thickened, so that in spite of the fact that this story had from beginning to end suggested obstruction at the level of the larynx, all the anatomic evidence clearly points to chronic obstruction for many years at the level of the cardia. There was nothing anatomic to explain chronic obstruction in the upper part of the esophagus. It is an extremely odd story for cardiospasm, and yet that is the only diagnosis that is consistent with the anatomic findings.

DR. SCHATZKI: You assume that he had spasm in the region of the acute ulcer?

DR. MALLORY: The facts that during life the esophagoscope would not pass and that after death it passed easily indicate to my mind that the obstruction must have been spastic.

DR. LERMAN: The ulceration and gingivitis could be consistent with a deficiency syndrome.

DR. MALLORY: Yes. This is the second case we have had here in a month of benign ulceration accompanied by symptoms of stenosis in a patient with generalized vitamin deficiency. Since we published the first case¹ my attention has been called to a paper by Merrill and Richards² from the Pondville Hospital. They report three cases referred to the clinic as cases of carcinoma of the esophagus because of dysphagia, obstruction and even x-ray findings suggestive of carcinoma that were cured by intensive vitamin therapy. In these cases objective evidence of neuritis of the ninth and tenth cranial nerves was obtained.

DR. MILLER: Does this round x-ray shadow represent ulceration through the wall and a pocket behind it?

DR. MALLORY: No; the ulceration was only 1.0 mm. deep. This is simply localized dilatation above a point of stricture.

The terminal episode was massive pulmonary edema with a considerable grade of hydrothorax attributable to acute circulatory failure.

DR. SWEET: There are two points that ought to be mentioned in regard to this patient. On the wards we thought he had carcinoma.

We have learned in recent years the vast importance of a diagnosis of esophagitis. In our experience, it is much more frequent in the lower third or quarter near the cardia than higher up. I have run across it in the differential diagnosis of carcinoma several times, and it is a significant finding.

Furthermore, I have acquired this impression about biopsy. If the biopsy specimen shows only an inflammatory process with x-ray evidence that looks like carcinoma in the upper portion of the esophagus, the lesion is unlikely to be carcinoma. In the lower portion of the esophagus it is likely to be a carcinoma that has grown up from the stomach into the esophageal wall with a submucosal extension. In such cases the esophagoscopist may obtain only mucous membrane, the carcinoma lying deeper. I doubt if that happens commonly, although within two weeks we had a case in which an esophageal carcinoma opposite the manubrium was diagnosed with difficulty. The first biopsy showed chronic inflammation, and the second tumor. I have the impression that this discrepancy does not occur so frequently in high lesions as it does in lower ones, but we must be on the lookout for the diagnosis of esophagitis at any level. I have seen several cases.

DR. MALLORY: It is of great practical importance not to assume that a case of this sort has carcinoma of the esophagus and is therefore hopeless.

CASE 29122

PRESENTATION OF CASE

An eighty-year-old retired grocer entered the hospital because of severe abdominal pain and constipation.

The patient was quite well until ten days before admission, when he became constipated despite the daily use of mineral oil. Five and a half days later he had two small bowel movements. The stools were brown but firmer than normal. Three days before entry he became slightly distended and developed generalized crampy abdominal pain. Several hours later he began to vomit a brownish fluid. The vomiting and pain continued unchanged to the time of admission. There was no pyuria, hematuria, chills, fever, jaundice, acholic, tarry or bloody stools.

The family history was noncontributory. For many years the patient had had an easily reducible left inguinal hernia, which a truss kept satisfactorily reduced.

Physical examination revealed a thin man who vomited frequently. The skin and mucous membranes were dry. The tongue was beefy red and dry. The chest was emphysematous, and the percussion note hyperresonant. A soft systolic murmur was audible at the apex. The abdomen was markedly distended, and the umbilical dimple flattened. Peristaltic waves were occasionally seen crossing the abdomen in the epigastrium and right lower quadrant. There was marked tympany over the entire abdomen. Only peristaltic rushes and loud borborygmi were audible, and these were loudest in the right half of the abdomen. There was generalized tenderness and rigidity. A large left direct inguinal hernia was easily reducible and was not tender. Rectal examination was not remarkable.

The blood pressure was 160 systolic, 75 diastolic. The temperature was 97.4°F., the pulse 80, and the respirations 20.

Examination of the blood revealed a red-cell count of 4,400,000 with a hemoglobin of 70 per cent, and a white-cell count of 8100 with 62 per cent polymorphonuclear leukocytes. The urine was normal. A blood Hinton test was negative. A roentgenogram showed that the abdomen was filled with gas-distended loops of small bowel; one loop in the pelvis had somewhat the appearance of sigmoid. The only air in the colon seemed to be in the rectum, which was not distended. Several hours after admission a barium enema readily filled the large bowel and revealed no abnormality.

Parenteral glucose and saline infusions and citrated-blood transfusions were administered, and a Miller-Abbott tube passed. The latter passed to the cecum and decompressed the dilated loops of small intestine.

On the ninth hospital day the Miller-Abbott tube was pulled back from the cecum for about 30 cm. into the ileum. Barium that was passed through the Miller-Abbott tube showed a slightly but definitely dilated ileum. There was a sudden narrowing of the ileum beginning about 15 cm. proximal to the ileocecal valve, and there was marked peristalsis of the ileum proximal to the point of narrowing. The amount of barium pushed through the terminal ileum was small, but the greater part of this portion of the ileum was seen to widen out at one time or another. An area approximately 2.5 cm. in length at the beginning of the narrowed ileum never showed distention; the mucosa in this area seemed to be preserved.

There was a similar area closer to the ileocecal valve, which showed some rigidity.

An operation was performed on the tenth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. LELAND S. MCKITTRICK: May we see the x-ray films? Be very careful what you say, Dr. Holmes, because a great deal depends on you.

DR. GEORGE W. HOLMES: This is the type of problem where the man who did the examination had a much better chance than I have. Furthermore, it is the type of case that the radiologist needs about an hour's study before making any real statement. I am saying this so that I will not mislead you, because anything I say will probably be wrong. There are, however, a few things that are obvious.

At the time the barium enema was given, the patient had a tremendously dilated small bowel and some gas in the large bowel; it does not look as if he had any gross pathology in the large bowel. I think we can agree with the man who made the examination that the lesion was low in the small bowel and close to the cecum. His description is rather better than anything that I can give you.

DR. MCKITTRICK: The cecum is normal?

DR. HOLMES: Yes. So far as I can tell the lesion was in the terminal ileum or outside the bowel involving the cecum, such as an appendiceal abscess.

I am surprised that the Miller-Abbott tube did not deflate the bowel. Even with the tube in place there was still a good deal of gas. They took a film of the chest, which I should say was normal for a man of his age.

DR. MCKITTRICK: We must start with the supposition or premise that this man had small-bowel obstruction. I do not believe it is possible to have the amount of dilated small bowel he had from a lesion in the large bowel, and in addition to that we have the confirmation that was given by the passage of barium from the rectum to the cecum, which showed a normal large bowel. Therefore we start with the premise that this man of eighty entered the hospital with small bowel obstruction. That may not be correct, but it is the only diagnosis we have any right to make.

If we start with the argument that he had small-bowel obstruction, what was the cause? I am perfectly frank to confess that I can talk myself out of any diagnosis that I wish to make. The only evidence we have is that the obstruction was in the terminal ileum. That is all right so far. Then the problem is, What was the nature of this man's obstruction? It seems to me there are a

couple of ways of approaching it. He could have had intrinsic cause of obstruction, that is, a tumor or an inflammatory lesion. If it was a tumor, it was probably either a carcinoma, a lymphoma or possibly a leiomyosarcoma; if it was an inflammatory lesion, it was probably either tuberculosis or enteritis. The only other intrinsic type of lesion is foreign body, and I do not think we need give much time to that. If it was not intrinsic, and I do not believe that we can say definitely that it was intrinsic, then it could have been extrinsic, as Dr. Holmes has said. The likeliest extrinsic lesions are an inflammatory process, such as appendiceal abscess, an adhesive band, the most frequent cause of acute small-bowel obstruction, and a tumor in an adjacent structure pressing from outside. It seems to me that somewhere in that list is the explanation for this man's disease.

Let us consider an adhesive band, which is the most frequent cause of obstruction. I shall be greatly disappointed if he had such a lesion. From the history, if it is correct, the first symptom he had was constipation. No one with acute small-bowel obstruction due to an adhesive band has a right to have constipation as the first symptom. The first symptom in 95 per cent of these cases is pain. Since this patient had constipation for three or four days before he had pain, it is impossible for me to accept that diagnosis, and I cross a line through it.

What about an inflammatory process? That is the thing on which I have been trying to get Dr. Holmes to help me out. He has done the best he could. Did this old man have appendicitis?

DR. HOLMES: I might give more help by interpreting what is in the record. It says that the mucosa appeared to be intact. That would make one think the lesion was outside the bowel. Then it says that the lumen changed considerably in size.

DR. MCKITTRICK: All except one place.

DR. HOLMES: Yes, but that changed a little, as I read it.

DR. MCKITTRICK: Let us make sure of the quotation. "An area approximately 2.5 cm. in diameter at the beginning of the narrowed ileum never showed distention." I interpret that to mean there was a place 2.5 cm. long that stayed as it was.

DR. HOLMES: Perhaps that is a better way of interpreting it. At any rate I believe they were thinking of something outside the mucosa.

DR. MCKITTRICK: Of course this question of appendiceal abscess is of greatest importance. Could this man have such a lesion? One teaching that we have always been brought up to believe is that appendicitis in an old man is a queer dis-

ease and never gives the classic picture. It comes when we least expect it. I was hopeful that something in the x-ray report would indicate a pressure defect on the cecum to suggest that this man did have an appendiceal abscess. At the moment I shall put a question mark beside this diagnosis.

Next is the question of intrinsic inflammation. Could this man have had a process in the wall of the bowel itself that had left the mucosa intact? It seems to me that if he had had regional enteritis, tuberculosis or anything of that sort he would have had some symptoms prior to ten days before admission. I do not believe one is entirely safe in excluding such a process because the history is short, but it does seem that the history is too rapidly progressive for that type of lesion. I am unwilling to accept either regional enteritis or tuberculosis as the cause of this man's trouble, and I shall cross them out.

Then we come to the group of tumors. Did the patient have carcinoma, lymphoma or leiomyosarcoma? Again, the story is too acute and rapidly progressive for carcinoma of the terminal ileum, unless it had intussuscepted. If it had, the initial symptom, I think, would have been pain and not constipation. So you see, I can talk myself out of everything I can think of. We can possibly attach some significance to one statement of the X-ray Department, namely, that the mucosa in this area was intact. If the mucosa was intact, the lesion could not have been cancer. It probably was not lymphoma. So I cross a line through that group, and that brings me back to the question of an external inflammatory process.

Was this appendicitis? I cannot answer the question. I do know this—there is nothing in the story inconsistent with it. Appendicitis can result in secondary obstruction. I do not know how much attention to pay to the widespread rigidity and tenderness. I do not know whether the subnormal temperature means anything, but I do not believe it does. The white-cell count and differential mean nothing. The patient was eighty years old, and a person may have appendiceal abscess at that age. I shall have to say that he had small-bowel obstruction, that the lesion was probably extrinsic and that the likeliest extrinsic lesion is an inflammatory process, probably originating in the appendix.

DR. E. PARKER HAYDEN: I should like to ask Dr. Holmes if lymphoma can be excluded on the lack of destruction of the mucosa. I believe that a normal mucosa can be found with lymphoma.

DR. HOLMES: That is true, but an ulcerative lesion can also be present. If one is trying to decide between carcinoma and lymphoma, and

if the mucosa is intact, the lesion is a little likelier to be lymphoma. Perhaps Dr. Mallory can answer that better than I can.

DR. TRACY B. MALLORY: There is one other neoplasm in this area that should be considered more seriously than those two, that is, carcinoid. The mucosa is never ulcerated with a carcinoid, but I think the pattern might be altered.

DR. MCKITTRICK: Do they occur in the terminal ileum?

DR. MALLORY: Yes; next to the appendix that is the favored spot, and I have seen one in an eighty-year-old man.

CLINICAL DIAGNOSIS

Mucocele of appendix, with mechanical obstruction.

DR. MCKITTRICK'S DIAGNOSIS

Abscess of appendix, with secondary small-bowel obstruction.

ANATOMICAL DIAGNOSIS

Mucocele of appendix, with mechanical obstruction.

PATHOLOGICAL DISCUSSION

DR. NATHAN D. MUNRO: After the Miller-Abbott tube was in place, the general pain, tenderness and spasm subsided. The patient later developed an indefinite tenderness in the right lower quadrant. The x-ray films were of considerable help. The differential diagnosis was much as Dr. McKittrick suggested. Dr. D. N. Sweeny operated and found a mucocele of the appendix, which was reported to show subacute inflammation. It was adherent to the terminal ileum and was evidently the cause of the obstruction.

DR. MALLORY: Before it was opened the mucocele was sufficiently distended to make a small but significant tumor mass.

DR. MCKITTRICK: May I add that I got the greatest satisfaction out of reading this case over because of the way it was handled. Here was an eighty-year-old man with small-bowel obstruction and distention who undoubtedly would have died promptly after an emergency operation. The passage of a Miller-Abbott tube, with relief of distention, and later x-ray visualization of the obstructed area were just the things to have done.

PROPAMIDINE—A NEW WOUND ANTISEPTIC

A RECENT issue of the *Lancet* focuses attention on a new antibacterial agent for topical application in infected wounds. In a study of the effect of the aromatic diamidine series on protozoa Fuller¹ noted that propamidine (4,4' diamidino diphenoxypropine dihydrochloride) also possessed an antibacterial effect. This substance has been carefully studied by Thrower and Valentine,² because its bacteriostatic action is not inhibited by peptones, tissue fluids, pus or para aminobenzoic acid. The lowest concentration of propamidine showing a clear bactericidal effect on hemolytic streptococci in pus was 0.003 to 0.005 per cent. For staphylococcal pus the effective concentration was 0.025 to

0.050 per cent. Studies of broth cultures suggested that the anaerobic gas producing bacilli were about as sensitive as staphylococci. In vitro phagocytic tests performed with defibrinated blood and staphylococci showed that phagocytosis was practically unaffected by 0.1 per cent propamidine, slightly reduced by 0.2 per cent and inhibited by 0.4 per cent. Even in a concentration of 0.4 per cent the leukocytes were not killed and the red cells were not hemolyzed. Thus it would appear that bactericidal concentrations of the drug are well below the cytotoxic level.

A clinical technique for the application of propamidine to wounds was evolved by trial on patients with osteomyelitis, infected burns and septic wounds of the soft parts. The wounds are cleansed with physiologic saline solution and are surgically exteriorized by incision, if necessary to ensure adequate contact of the drug with all infected surfaces. One tenth per cent propamidine in a base consisting of 45 per cent methyl cellulose in water is applied as a jelly to the wound surface and sealed over with vaseline gauze. The wound is dressed and similarly treated on alternate days for a total of five treatments. Care must be taken to avoid contact with the intact skin lest it become inflamed and irritated by the jelly. Treatment for more than ten days or concentrations above 0.1 per cent have led to superficial necrosis of the granulation tissue. It is apparent that the full antibacterial effect is readily obtained within the ten day period. Streptococci disappear first and are followed by staphylococci. Proteus and pyocyanus bacilli usually persist but do not appear to retard healing. Wounds with persistent sinuses or incomplete healing after the ten day period of treatment are judged ready for operative removal of foreign bodies, sequestrectomy or skin grafting.

Propamidine jelly was released for trial at an EMS hospital in 5 cases of infected ulcer and casualty wounds and 8 cases of burns.³ The infected ulcers and wounds became sterile, or nearly so, in four to ten days and thereafter healed rapidly or were successfully grafted. The burned patients were relieved of pain, second degree areas

healed within ten days, and infection did not occur. Morley and Bentley⁴ obtained similar results in 7 cases of recent burn and are of the opinion that propamidine was effective in the treatment of older burns infected with sulfonamide-resistant organisms.

McIndoe and Tilley⁵ used propamidine jelly in 11 patients with secondary hemolytic streptococcus infections of wounds and burns not improved by local applications of Eusol and sulfanilamide or by saline dressings. Recently infected wounds cleared more rapidly than older ones, but the streptococci disappeared from all within the ten-day period. In 3 cases there was partial loss of subsequent skin grafts from staphylococcal infection.

It is to be hoped that further trial of propamidine will confirm these encouraging reports. There can be little doubt that the drug will be exhaustively studied in the near future. No success has attended the intravenous use of propamidine in experimental streptococcal infections in mice.¹ Furthermore, clinicians will do well to note that drugs of this series have produced circulatory collapse or violent itching after the intravenous injection of 2 mg. per kilogram of body weight for sleeping sickness.⁶ It seems likely that absorption of topically applied propamidine will be slight, but this is an inference from the behavior of the related and fluorescent compound, stilbamidine,^{7, 8} which is stored in the liver and kidneys and is absorbed by the red blood cells. The possibility of immediate and late toxic effects is apparent. Until more experience has been gained it is unwarranted to use the drug for large wounds or in patients with impending shock.

BOSTON'S AMPHIBIAN HOSPITAL

A SEA-GIRT country such as ours can boast of more than one floating hospital—of which the Navy's hospital ships are the present outstanding examples; only Boston can boast of an amphibian hospital that has breasted the unruly ocean for season after season, and finally climbed onto the land, not to rest but there to continue its labors. A unique Boston charity, the Boston Floating Hospital has now dropped the limitations imposed by the pure charitableness of its nature and has made its facilities available to those who can pay.
